Why Topic Modeling?

Information Overload

As more information becomes available, it becomes more difficult to find and discover what we need.

Why Topic Modeling?

Information Overload

As more information becomes available, it becomes more difficult to find and discover what we need.

Topic Modeling

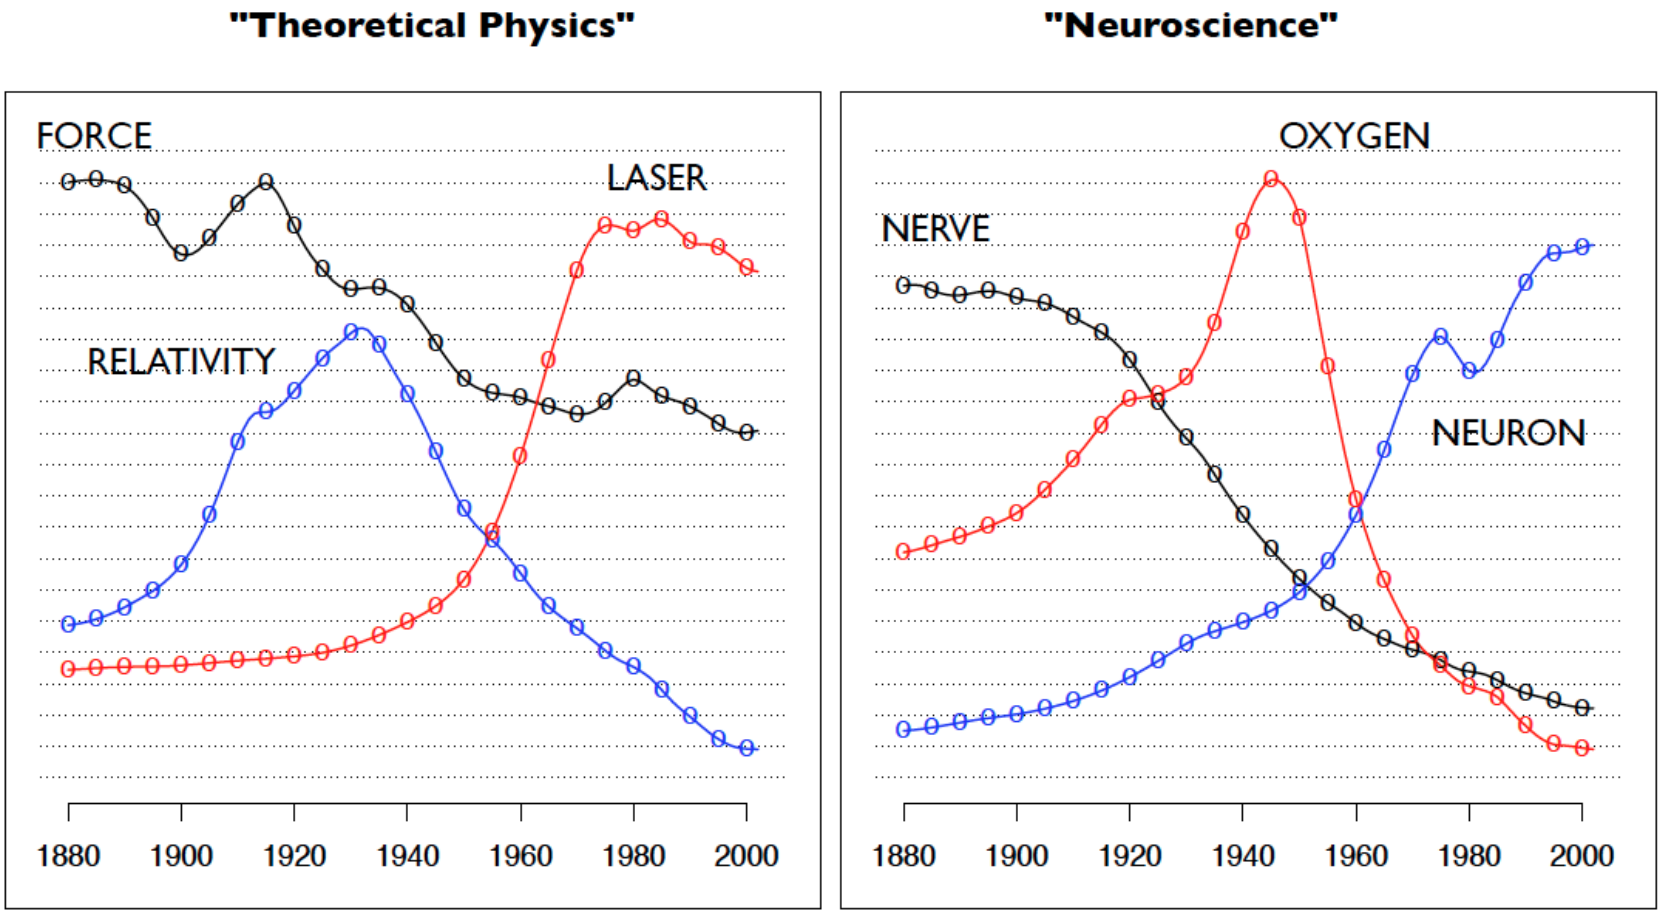
Provides methods for automatically organizing, understanding, searching and summarizing large electronic archives

- Discover the hidden themes that pervade the collection
- Annotate the documents according to those themes
- Use annotations to organize, summarize, and search the texts

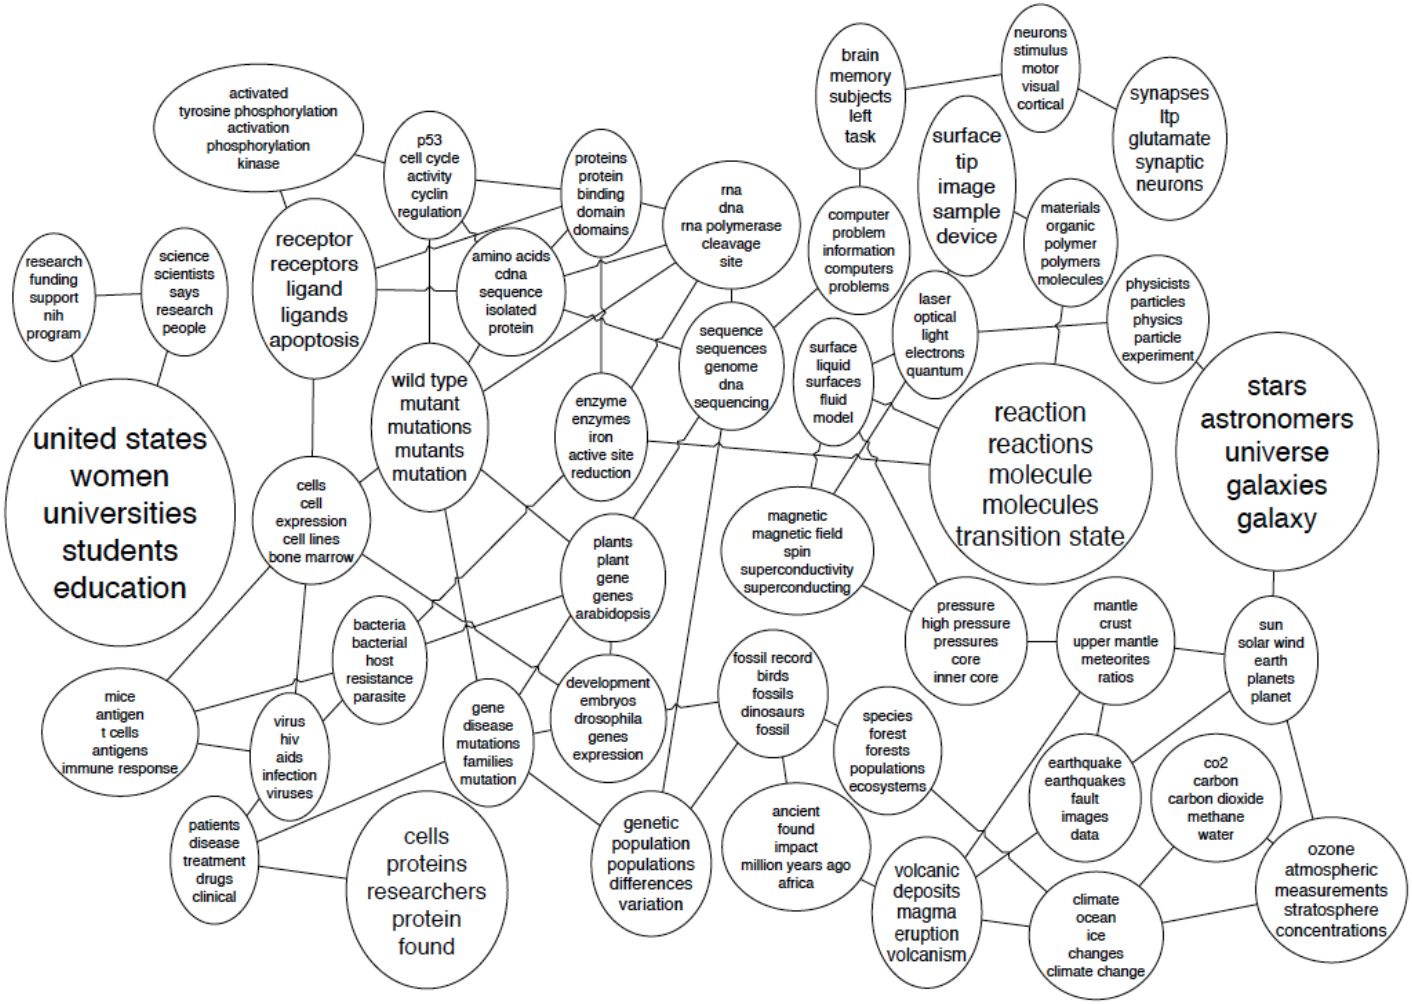
Applications: Discover Topics from a corpus

human	evolution	disease	computer
genome	evolutionary	host	models
dna	species	bacteria	information
genetic	organisms	diseases	data
genes	life	resistance	computers
sequence	origin	bacterial	system
gene	biology	new	network
molecular	groups	strains	systems
sequencing	phylogenetic	control	model
map	living	infectious	parallel
information	diversity	malaria	methods
genetics	group	parasite	networks
mapping	new	parasites	software
project	two	united	new
sequences	common	tuberculosis	simulations

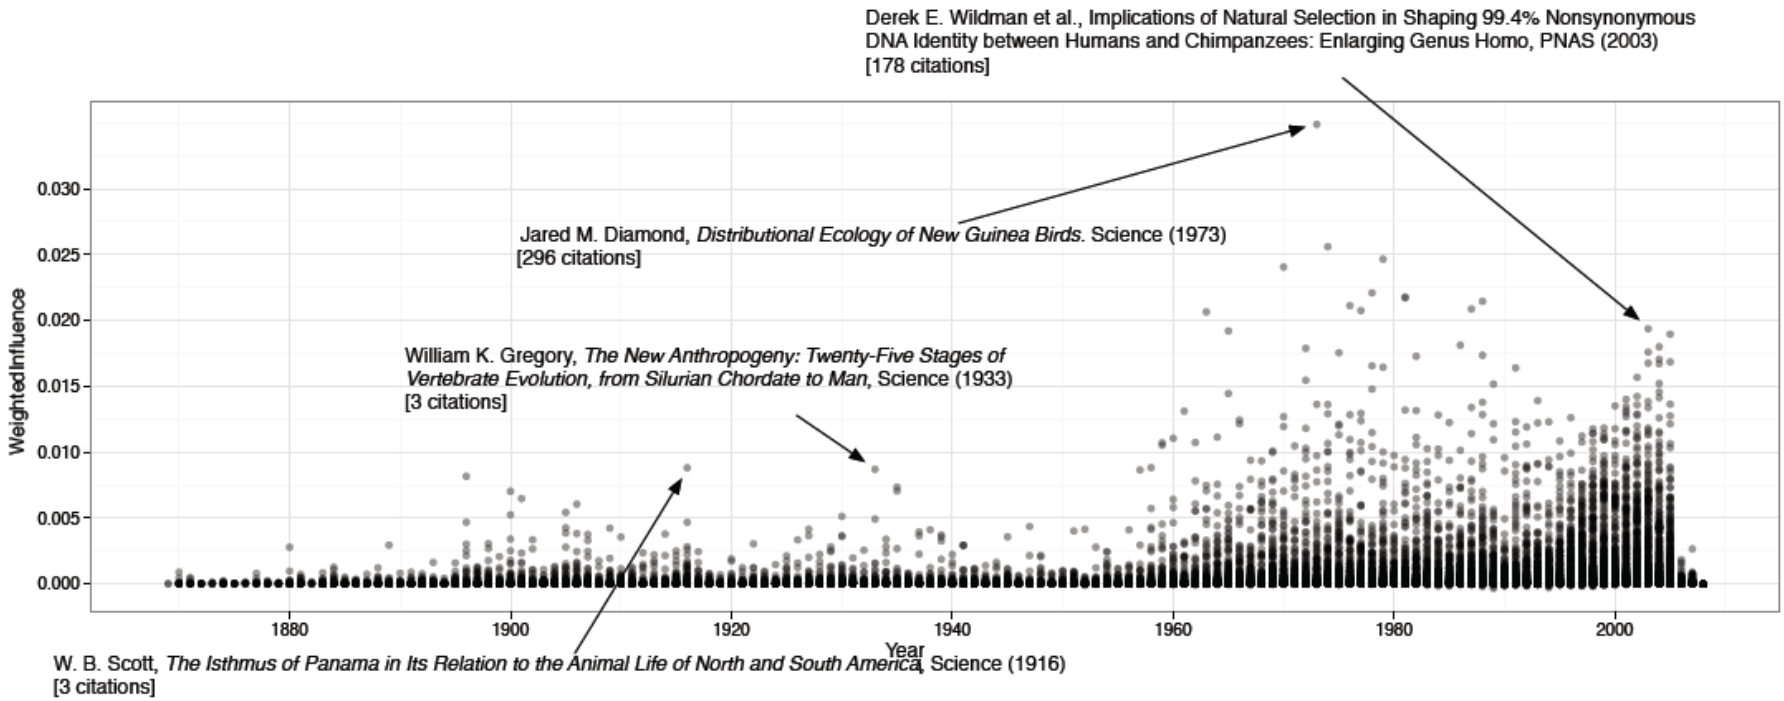
Applications: Model the evolution of topics over time



Applications: Model connections between topics



Applications: Discover influential articles



Link Prediction using Relational Topic Models

Markov chain Monte Carlo convergence diagnostics: A comparative review

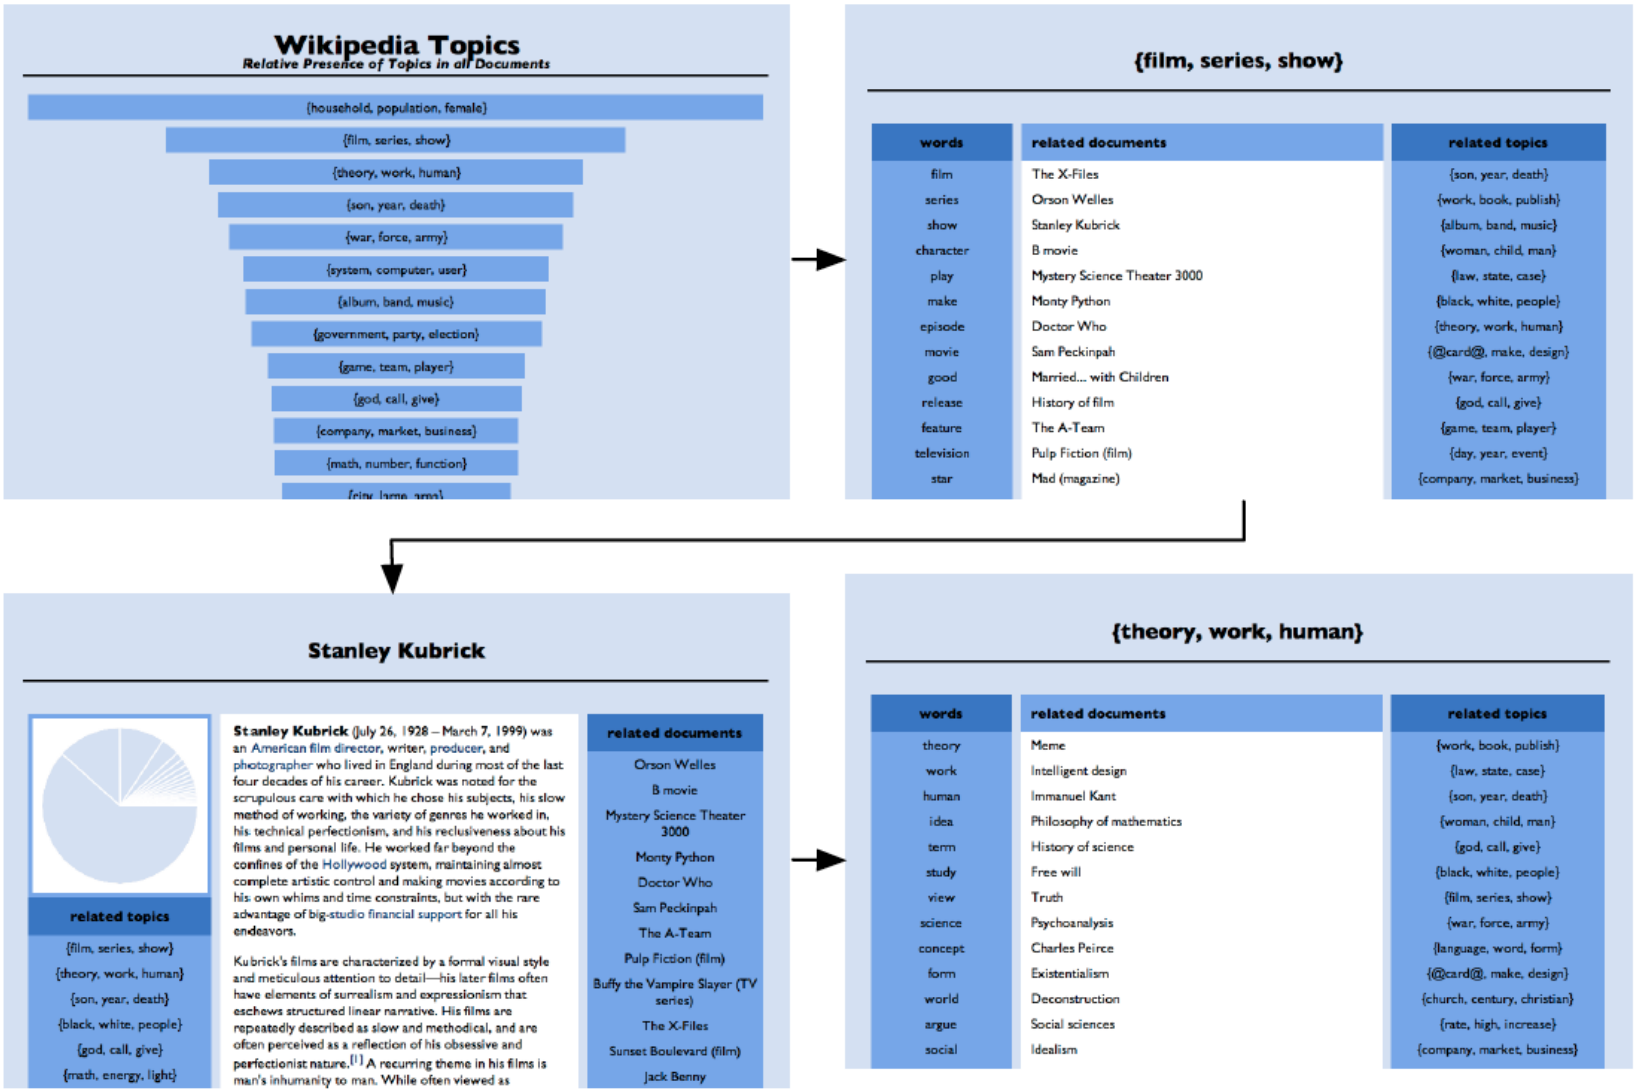
Exact Bound for the Convergence of Metropolis Chains Self regenerative Markov chain Monte Carlo **Minorization conditions and convergence rates for Markov chain Monte Carlo** Gibbs-markov models Auxiliary variable methods for Markov chain Monte Carlo with applications Markov Chain Monte Carlo Model Determination for Hierarchical and Graphical Models Mediating instrumental variables A qualitative framework for probabilistic inference Adaptation for Self Regenerative MCMC	**LDA + Regression**

Applications: Organize and browse large corpora



Intuition: Documents exhibit multiple topics

Seeking Life's Bare (Genetic) Necessities

COLD SPRING HARBOR, NEW YORK—How many genes does an organism need to survive? Last week at the genome meeting here,* two genome researchers with radically different approaches presented complementary views of the basic genes needed for life. One research team, using computer analyses to compare known genomes, concluded that today's organisms can be sustained with just 250 genes, and that the earliest life forms required a mere 128 genes. The other researcher mapped genes in a simple parasite and estimated that for this organism, 800 genes are plenty to do the job—but that anything short of 100 wouldn't be enough.

Although the numbers don't match precisely, those predictions "are not all that far apart," especially in comparison to the 75,000 genes in the human genome, notes Siv Andersson of Uppsala University in Sweden, who arrived at the 800 number. But coming up with a consensus answer may be more than just a genetic numbers game, particularly as more and more genomes are completely mapped and sequenced. "It may be a way of organizing any newly sequenced genome," explains Arcady Mushegian, a computational molecular biologist at the National Center for Biotechnology Information (NCBI) in Bethesda, Maryland. Comparing an

Knowing that this article blends those topics would help situate it in a collection of scientific articles

Topic Model: Basic Idea

A generative statistical model that captures this intuition.

Generative Model

Documents are mixture of topics, where a topic is a probability distribution over words.

Topic Model: Basic Idea

A generative statistical model that captures this intuition.

Generative Model

Documents are mixture of topics, where a topic is a probability distribution over words.
genetics topic has words about genetics with high probability and the *evolutionary biology* topic has words about evolutionary biology with high probability.

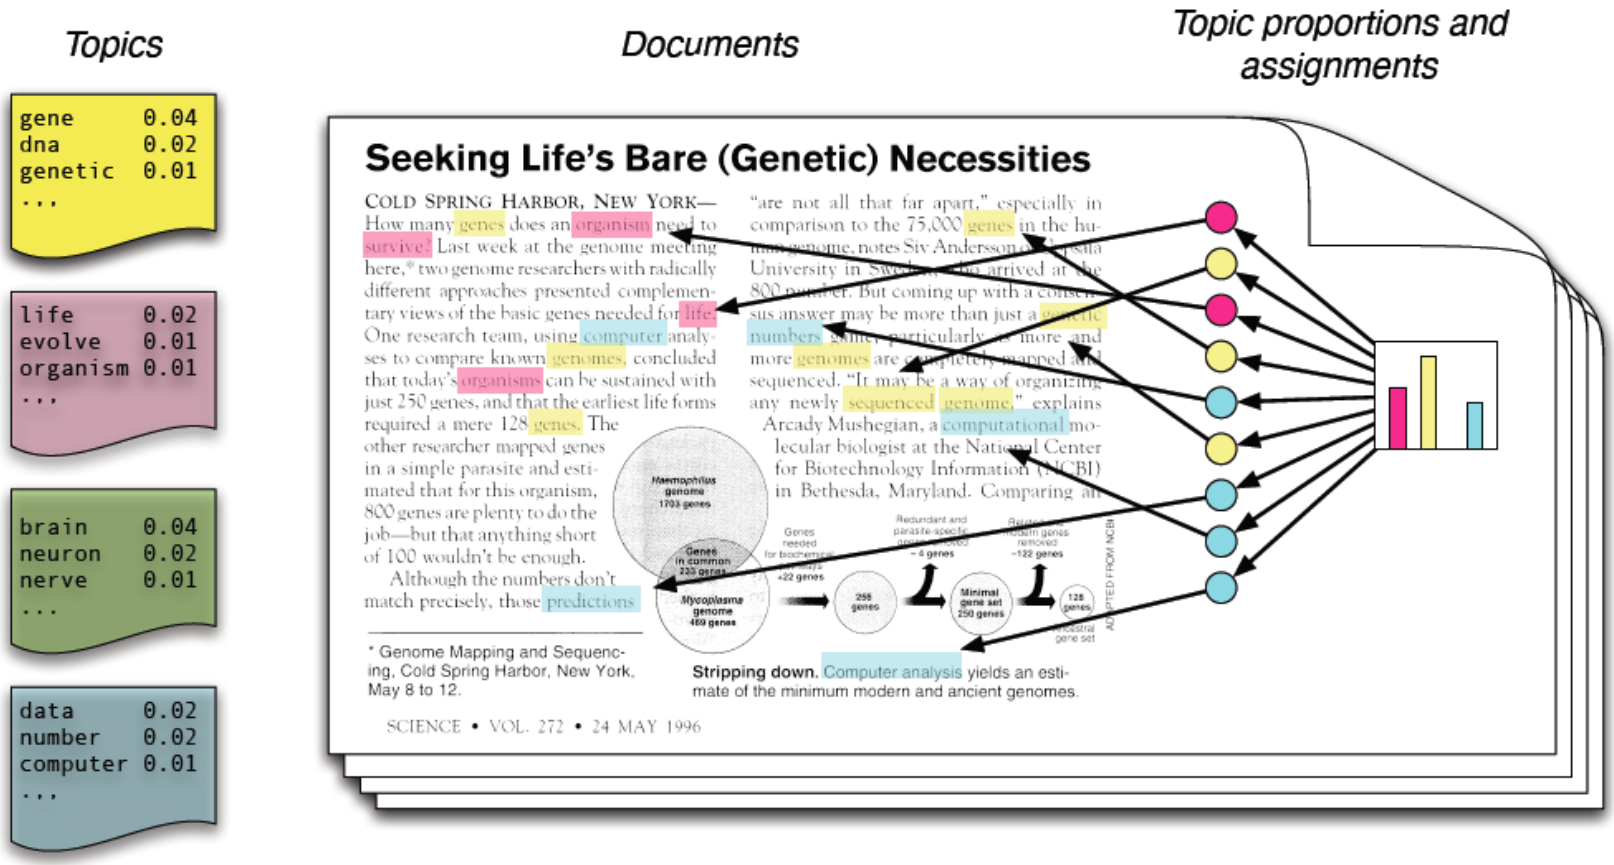
Topic Model: Basic Idea

A generative statistical model that captures this intuition.

Generative Model

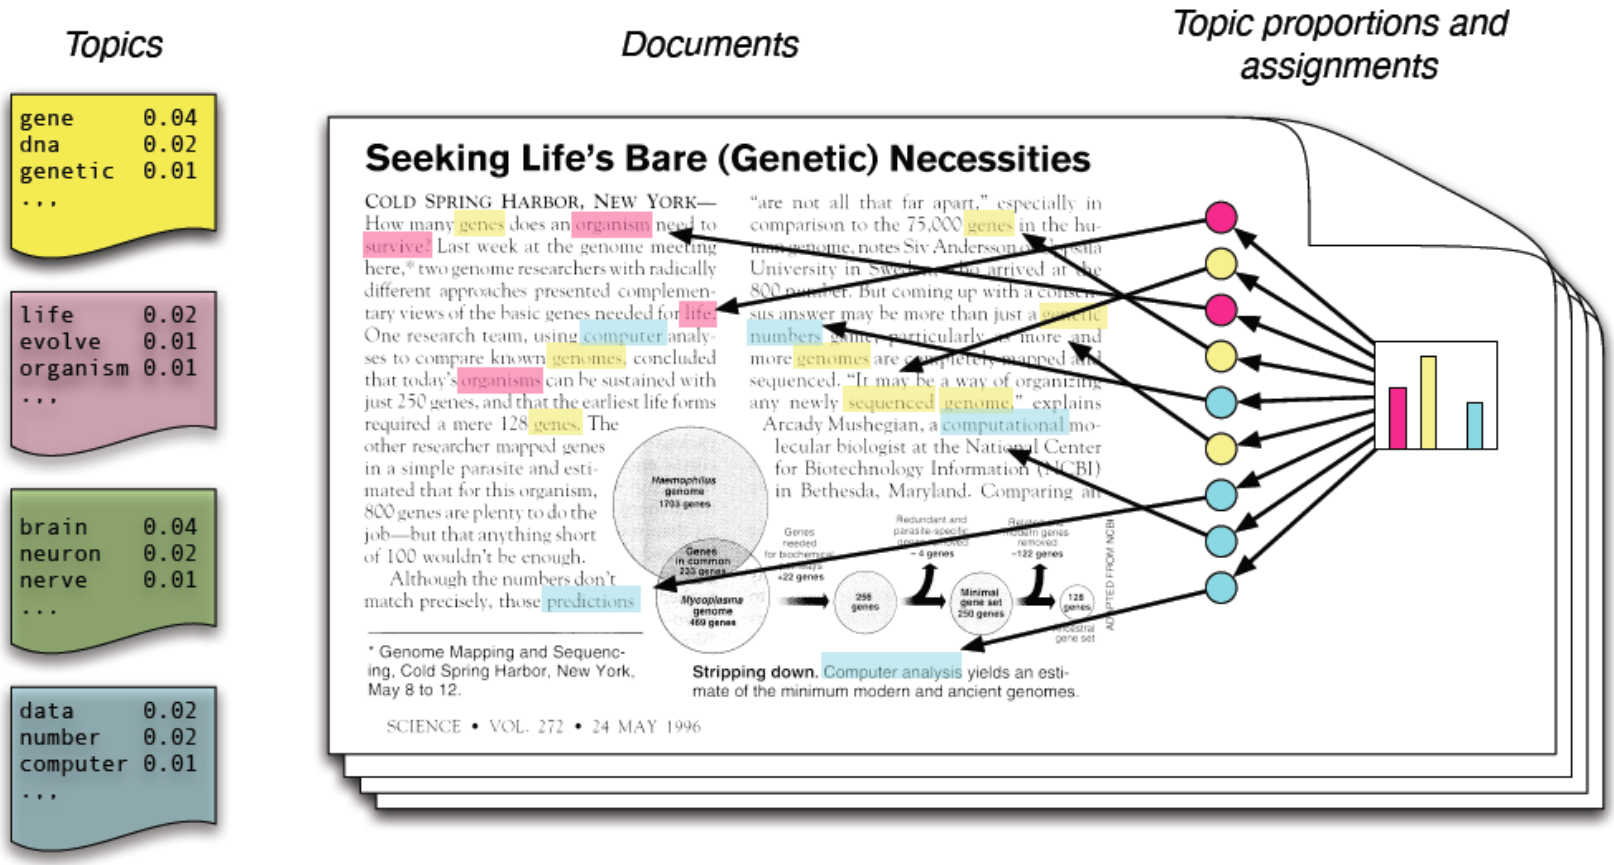
Documents are mixture of topics, where a topic is a probability distribution over words.
genetics topic has words about genetics with high probability and the *evolutionary biology* topic has words about evolutionary biology with high probability.
Technically, the generative model assumes that the topics are generated first, before the documents.

Generative Model for LDA



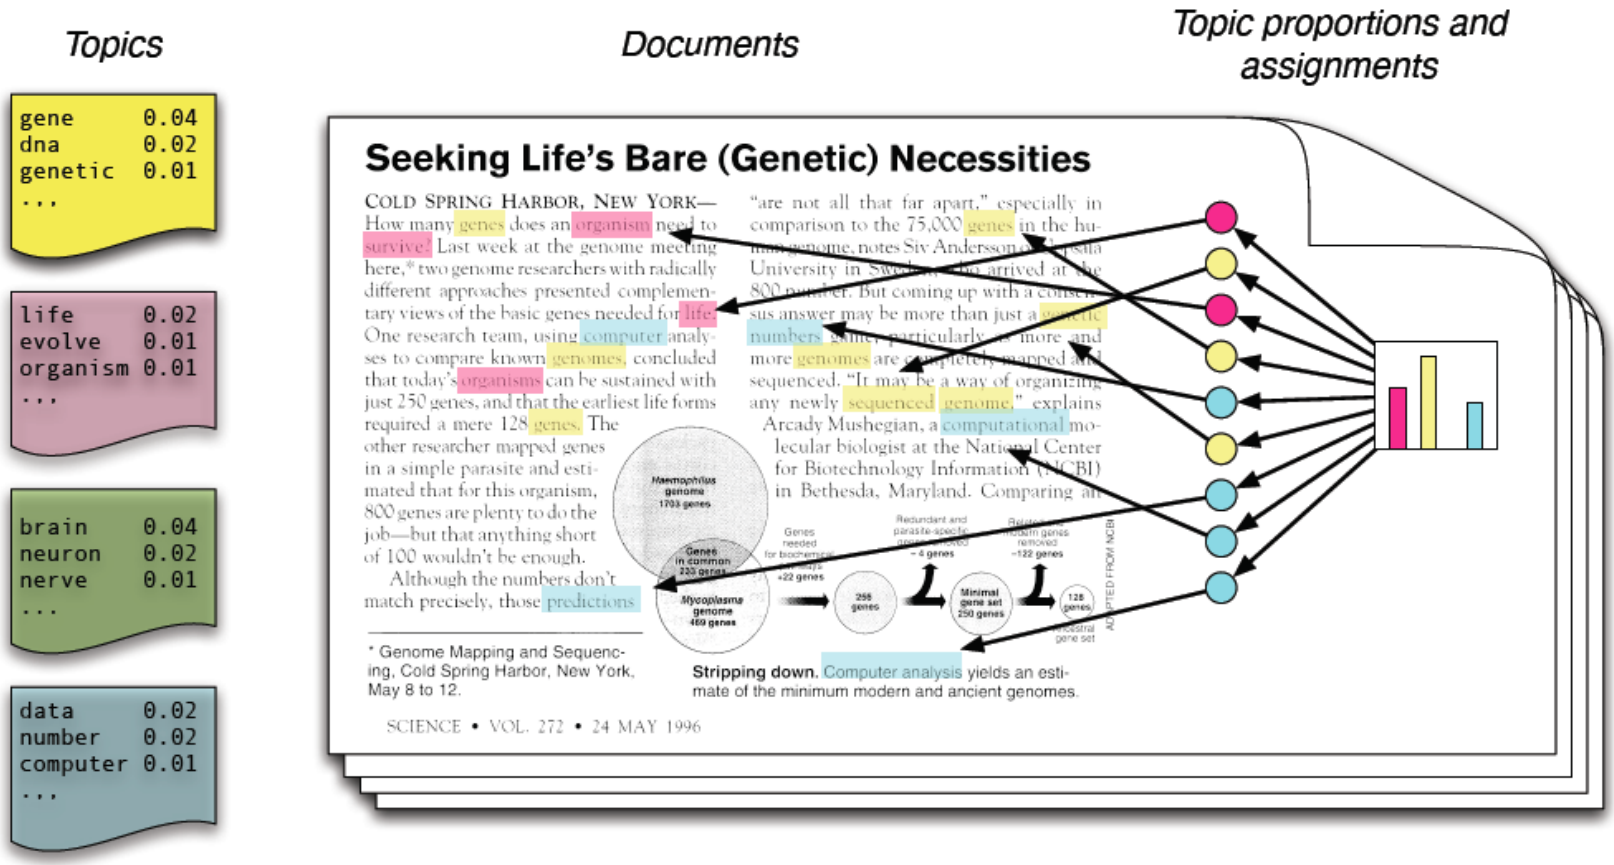
- Each **topic** is a distribution over words
- Each **document** is a mixture of corpus-wide topics
- Each **word** is drawn from one of those topics

Generative Model for LDA



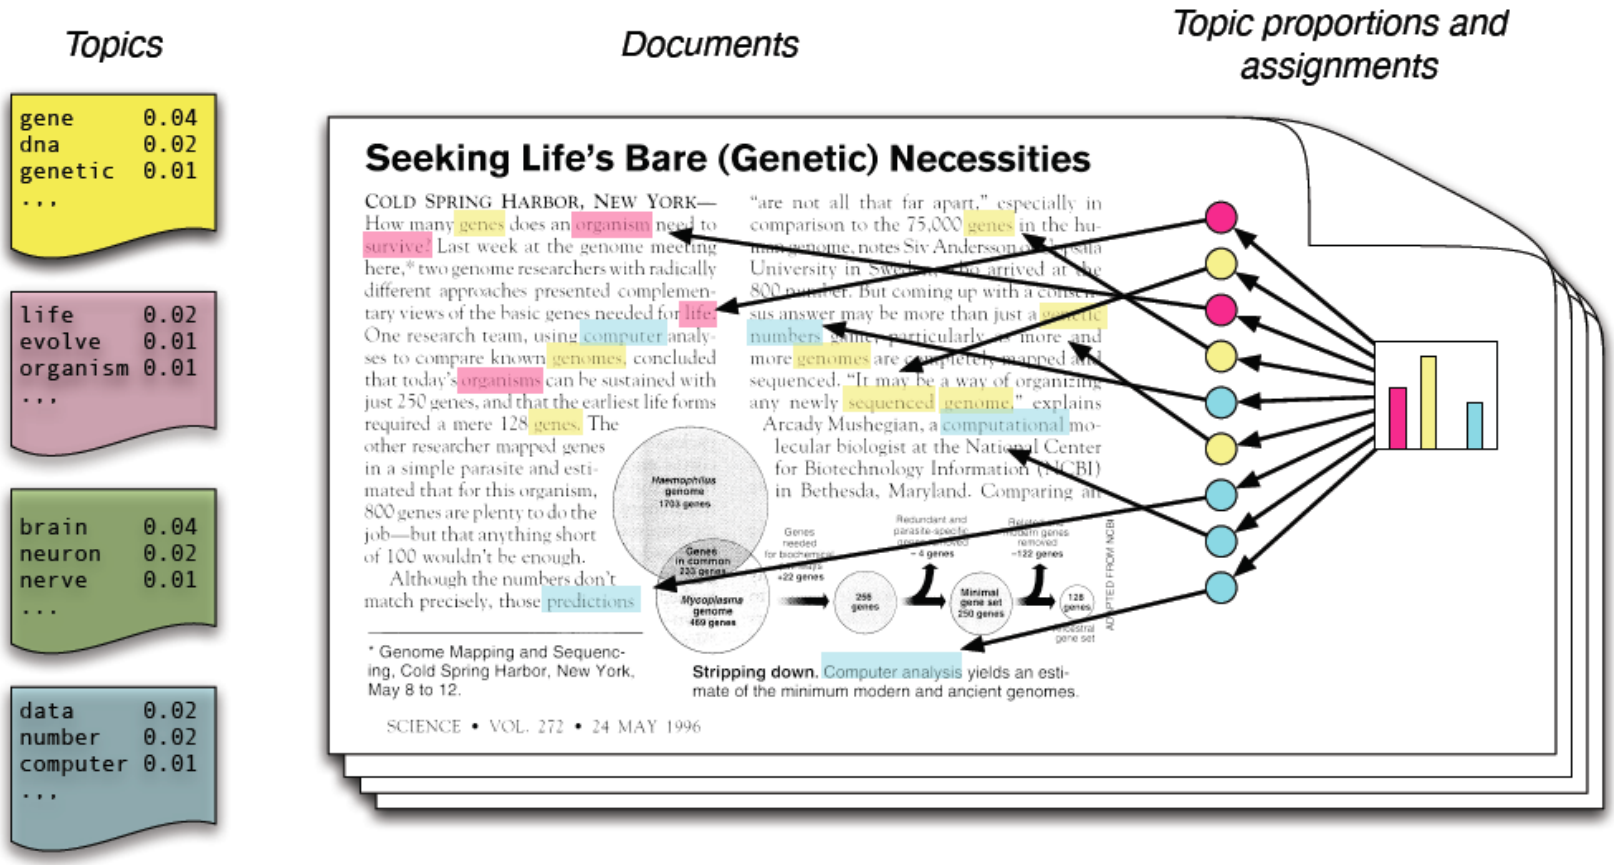
- Each **topic** is a distribution over words
- Each **document** is a mixture of corpus-wide topics
- Each **word** is drawn from one of those topics

Generative Model for LDA



- Each **topic** is a distribution over words
- Each **document** is a mixture of corpus-wide topics
- Each **word** is drawn from one of those topics

Generative Model for LDA



- Each **topic** is a distribution over words
- Each **document** is a mixture of corpus-wide topics
- Each **word** is drawn from one of those topics

What does the statistical model reflect?

- All the document in the collection share the same set of topics, but each document exhibits those topics in different proportions
- Each word in each document is drawn from one of the topics, where the selected topic is chosen from the per-document distribution over topics

What does the statistical model reflect?

- All the document in the collection share the same set of topics, but each document exhibits those topics in different proportions
- Each word in each document is drawn from one of the topics, where the selected topic is chosen from the per-document distribution over topics

In the example article, the distribution over topics would place probability on *genetics*, *data analytics* and *evolutionary biology*, and each word is drawn from one of those three topics.

Real Inference with LDA for the example article

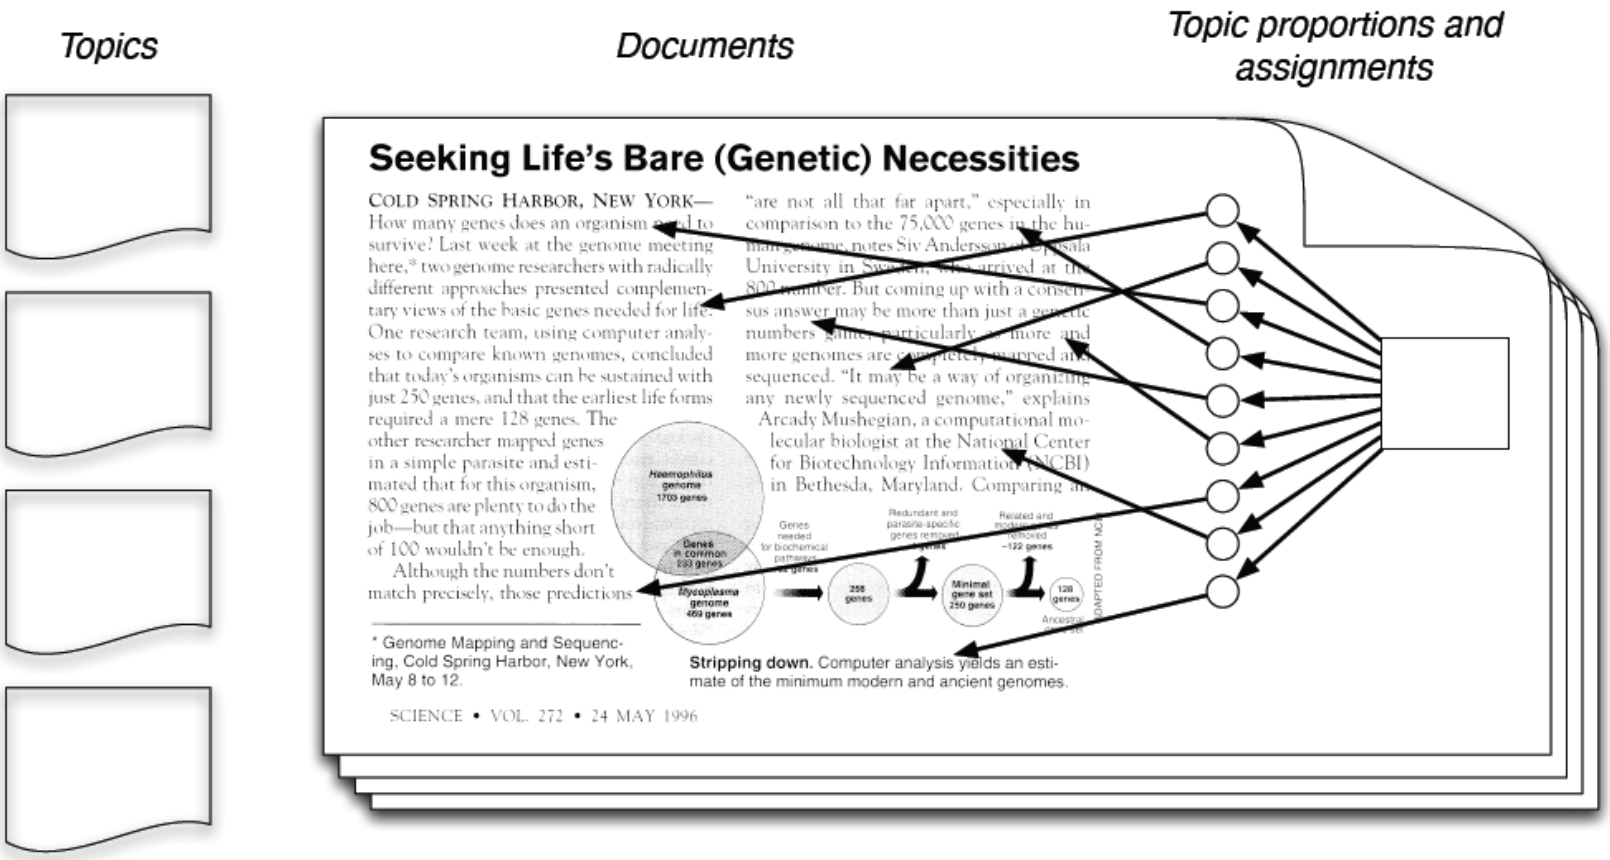
information	diversity	malaria	methods
genetics	group	parasite	networks
mapping	new	parasites	software
project	two	united	new
sequences	common	tuberculosis	simulations

Central Problem of LDA

- The documents themselves are observed, while the topic structure - the topics, per-document topic distributions, and the per-document per-word topic assignments - is *hidden structure*.
- The central computational problem is to use the observed documents to infer the hidden topic structure, i.e. *reversing* the generative process.

Goal: The posterior distribution



Infer the hidden variables

Compute their distribution conditioned on the documents

Topics from TASA corpus

Documents with different content can be generated by choosing different distributions over topics.

- Equal probability to first two topics:

Topics from TASA corpus

Documents with different content can be generated by choosing different distributions over topics.

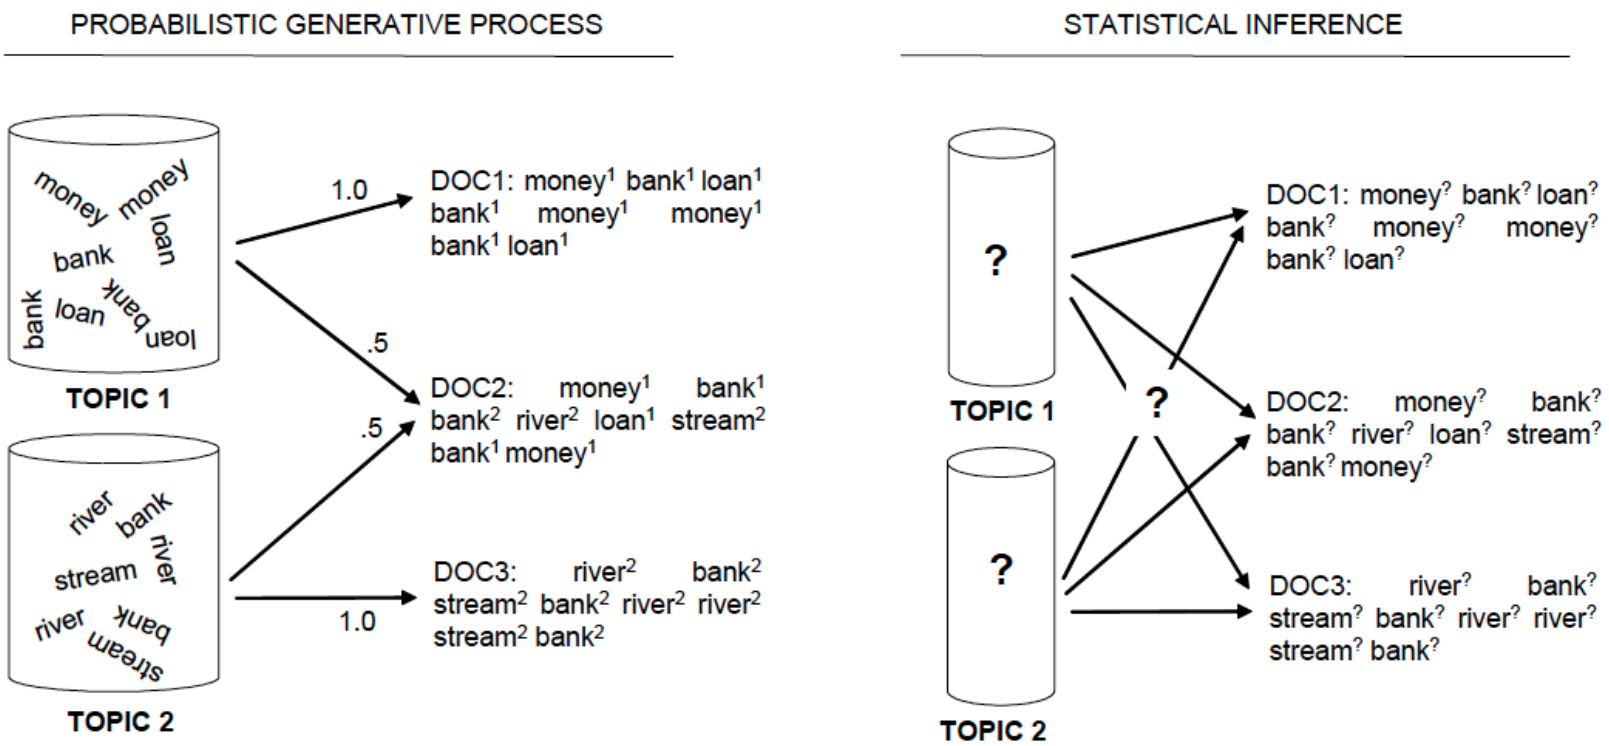
- Equal probability to first two topics: about a person who has taken too many drugs and how that affected color perceptions.
- Equal probability to the last two topics:

Topics from TASA corpus

Documents with different content can be generated by choosing different distributions over topics.

- Equal probability to first two topics: about a person who has taken too many drugs and how that affected color perceptions.
- Equal probability to the last two topics: about a person who experienced a loss of memory, which required a visit to the doctor.

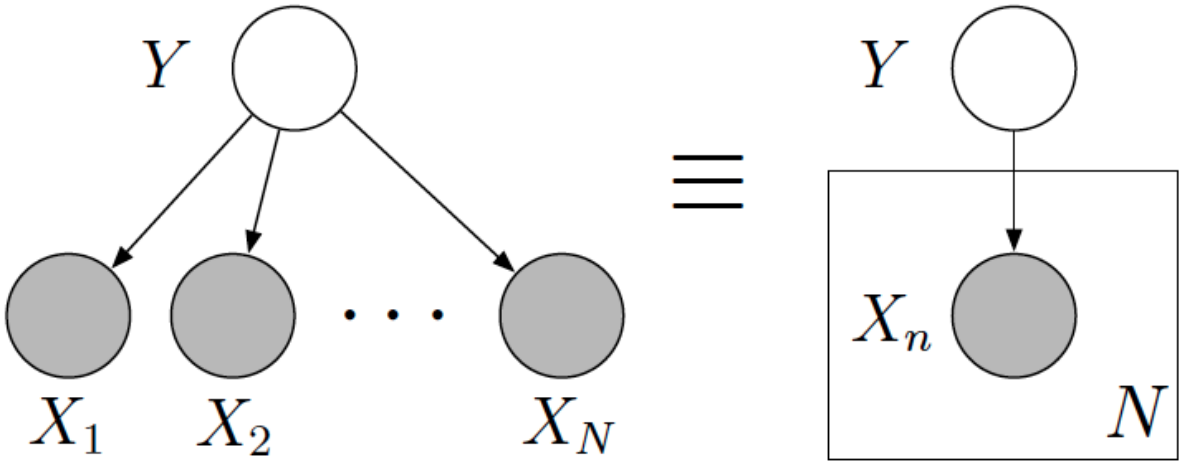
Generative model and statistical inference



Important points

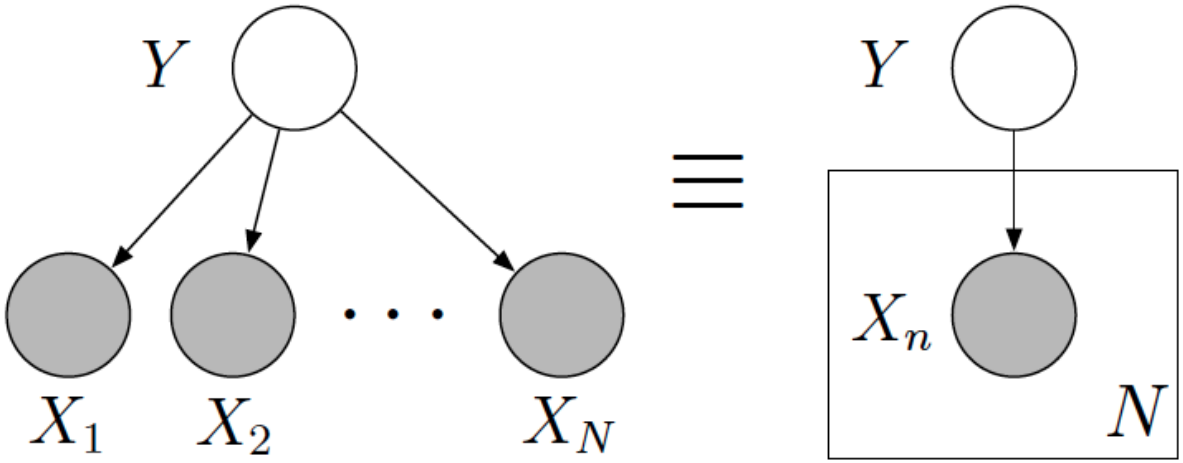
- *bag-of-words assumption:* The generative process does not make any assumptions about the order of words in the documents.
- *capturing polysemy:* The way that the model is defined, there is no notion of mutual exclusivity that restricts words to be part of one topic only. Ex: both ‘money’ and ‘river’ topics can give high probability to the word ‘bank’.

Graphical Model (Notation)



- Nodes are random variables
- Edges denote possible dependence
- Observed variables are shaded
- Plates denote replicated structure

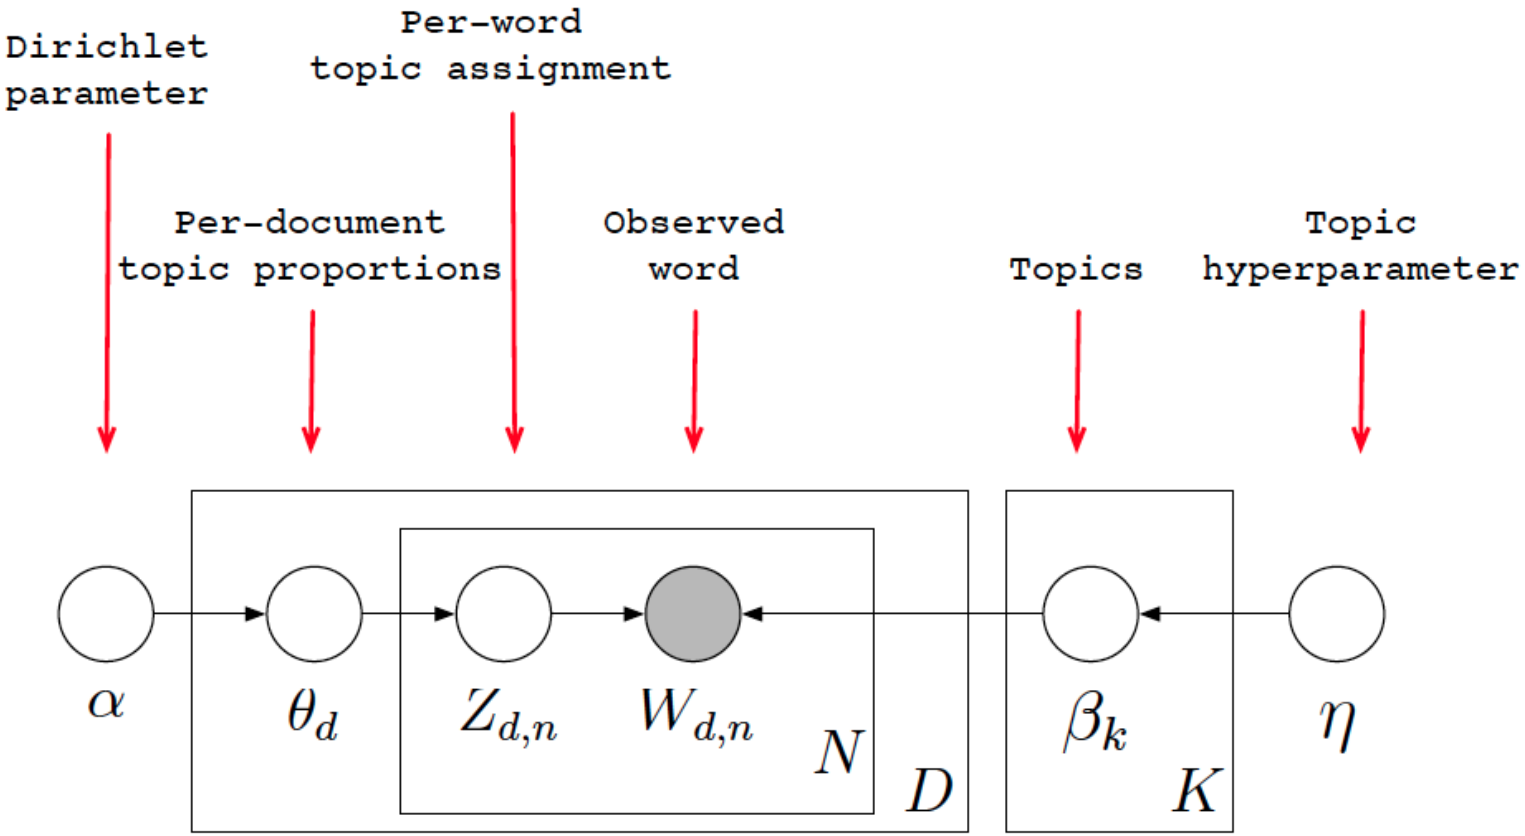
Graphical Model (Notation)



- Structure of the graph defines the pattern of conditional dependence between the ensemble of random variables
- E.g., this graph corresponds to

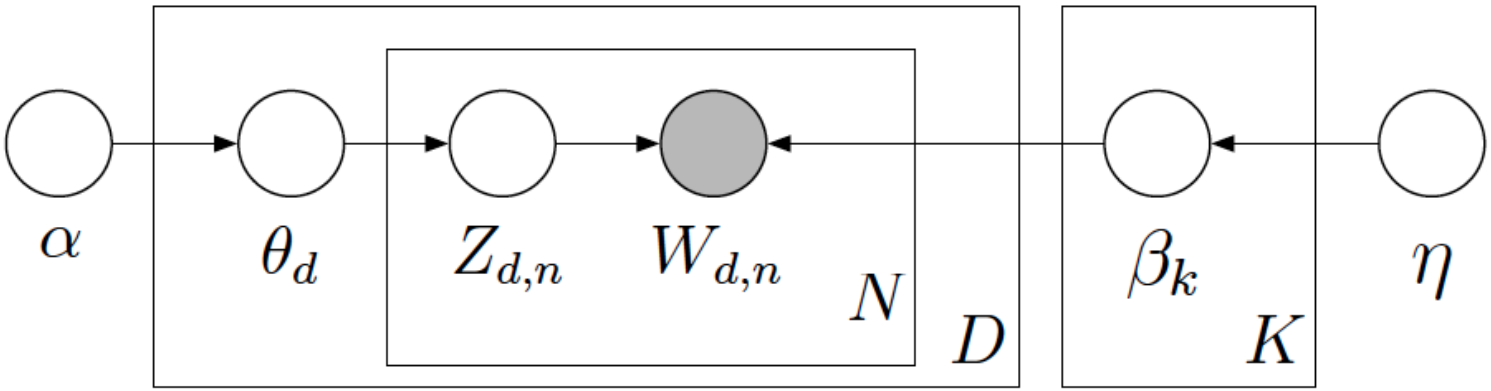
$$p(y, x_1, \ldots, x_N) = p(y) \prod_{n=1}^{N} p(x_n|y)$$

LDA: Graphical Model



Each piece of the structure is a random variable.

Latent Dirichlet Allocation: Generative Model



1. Draw each topic $\beta_i \sim \text{Dir}(\eta)$, for $i \in \{1, \ldots, K\}$.
2. For each document:
   1. Draw topic proportions $\theta_d \sim \text{Dir}(\alpha)$.
   2. For each word:
      1. Draw $Z_{d,n} \sim \text{Mult}(\theta_d)$.
      2. Draw $W_{d,n} \sim \text{Mult}(\beta_{z_{d,n}})$.

What is Latent Dirichlet Allocation (LDA)?

- 'Latent' has the same sense in LDA as in Latent semantic indexing, i.e. capturing topics as latent variables
- The distribution that is used to draw the per-document topic distributions is called a *Dirichlet distribution*. This result is used to allocate the words of the documents to different topics.

What is Latent Dirichlet Allocation (LDA)?

- 'Latent' has the same sense in LDA as in Latent semantic indexing, i.e. capturing topics as latent variables
- The distribution that is used to draw the per-document topic distributions is called a *Dirichlet distribution*. This result is used to allocate the words of the documents to different topics.

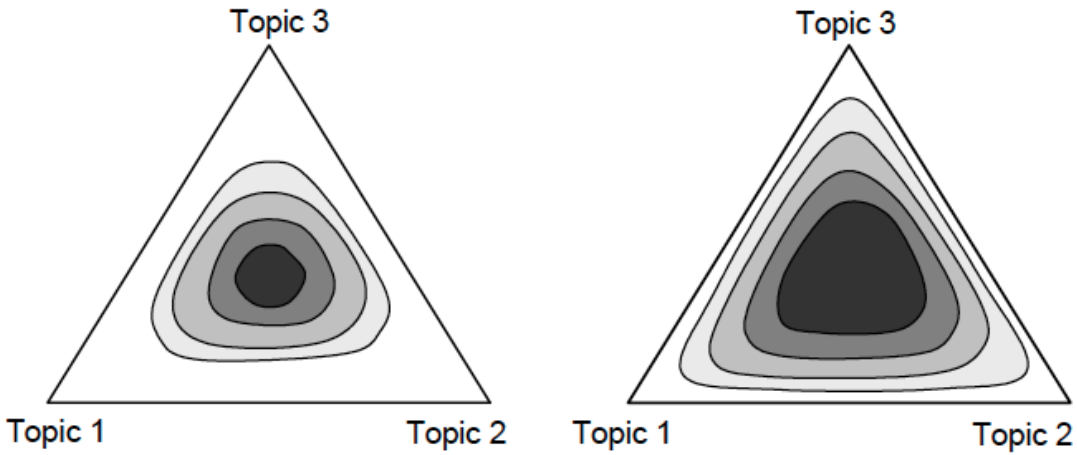
Dirichlet Distribution

The Dirichlet distribution is an exponential family distribution over the simplex, i.e. positive vectors that sum to one

$$p(\theta \mid \vec{\alpha}) = \frac{\Gamma\left(\sum_i \alpha_i\right)}{\prod_i \Gamma(\alpha_i)} \prod_i \theta_i^{\alpha_i - 1}$$

Dirichlet Distribution

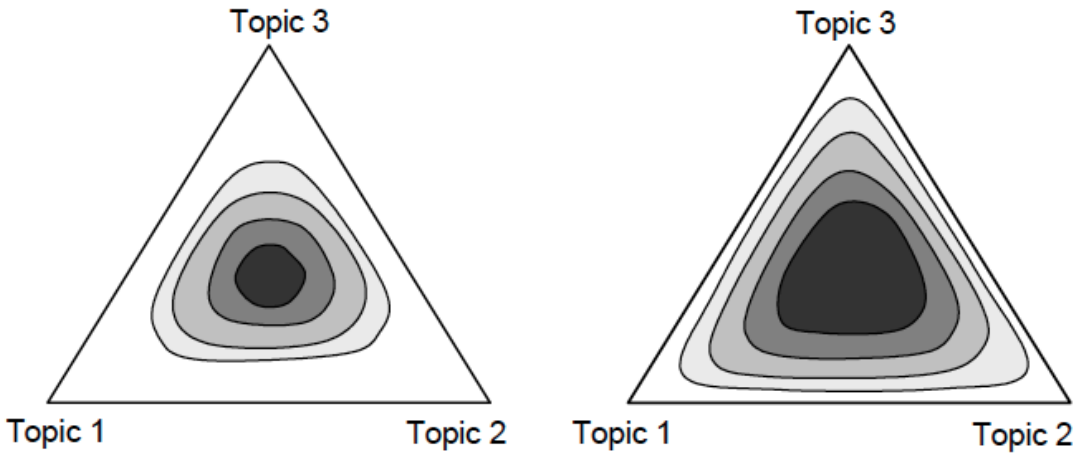
$$p(\theta \mid \vec{\alpha}) = \frac{\Gamma\left(\sum_i \alpha_i\right)}{\prod_i \Gamma(\alpha_i)} \prod_i \theta_i^{\alpha_i - 1}$$



α_is: **hyper-parameters of the model which can be interpreted as:** α_j can be interpreted as an observation count for the number of times topic j is sampled in a document

Dirichlet Distribution

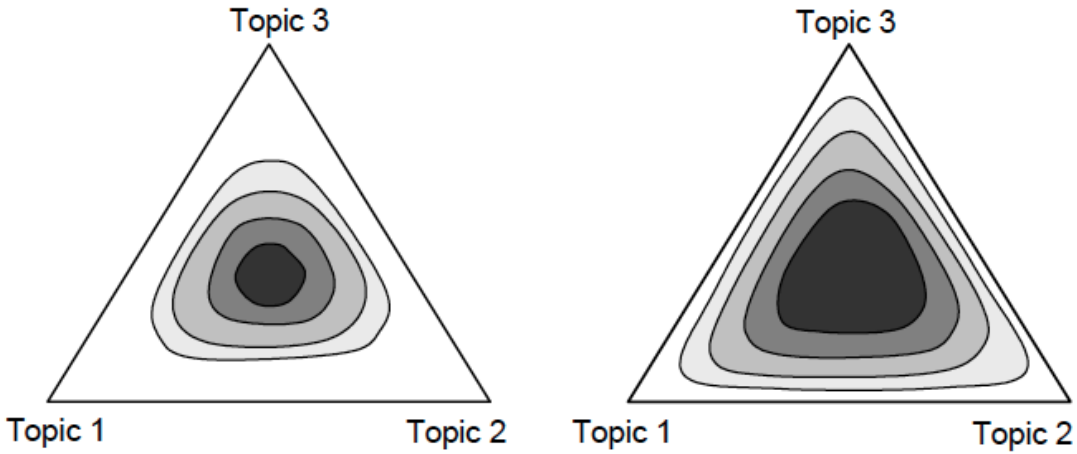
$$p(\theta \mid \vec{\alpha}) = \frac{\Gamma\left(\sum_i \alpha_i\right)}{\prod_i \Gamma(\alpha_i)} \prod_i \theta_i^{\alpha_i - 1}$$



α_is: **hyper-parameters of the model which can be interpreted as:** These priors can be interpreted as forces in the topic distributions with higher α moving the topics away from the corners of the simplex

Dirichlet Distribution

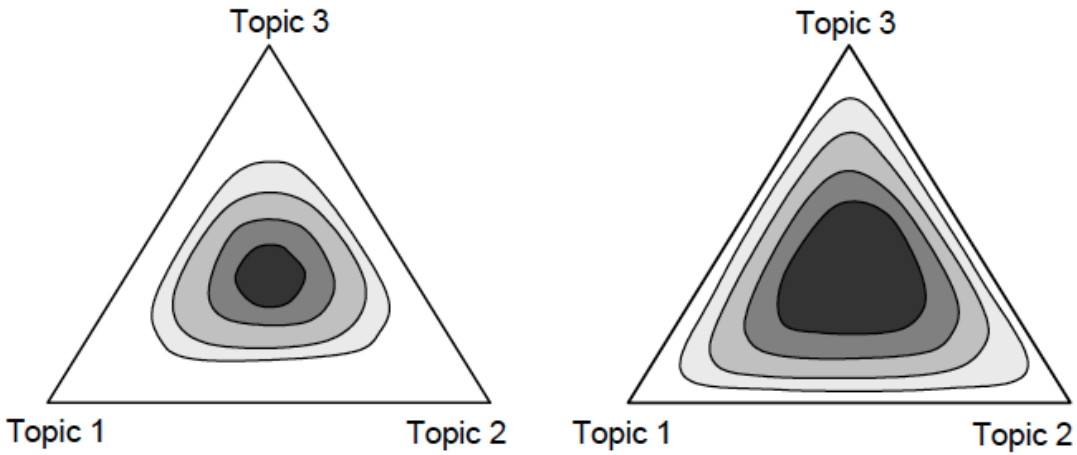
$$p(\theta \mid \vec{\alpha}) = \frac{\Gamma\left(\sum_i \alpha_i\right)}{\prod_i \Gamma(\alpha_i)} \prod_i \theta_i^{\alpha_i - 1}$$



α_is: **hyper-parameters of the model which can be interpreted as:** When $\alpha < 1$, there is a bias to pick topic distributions favoring just a few topics

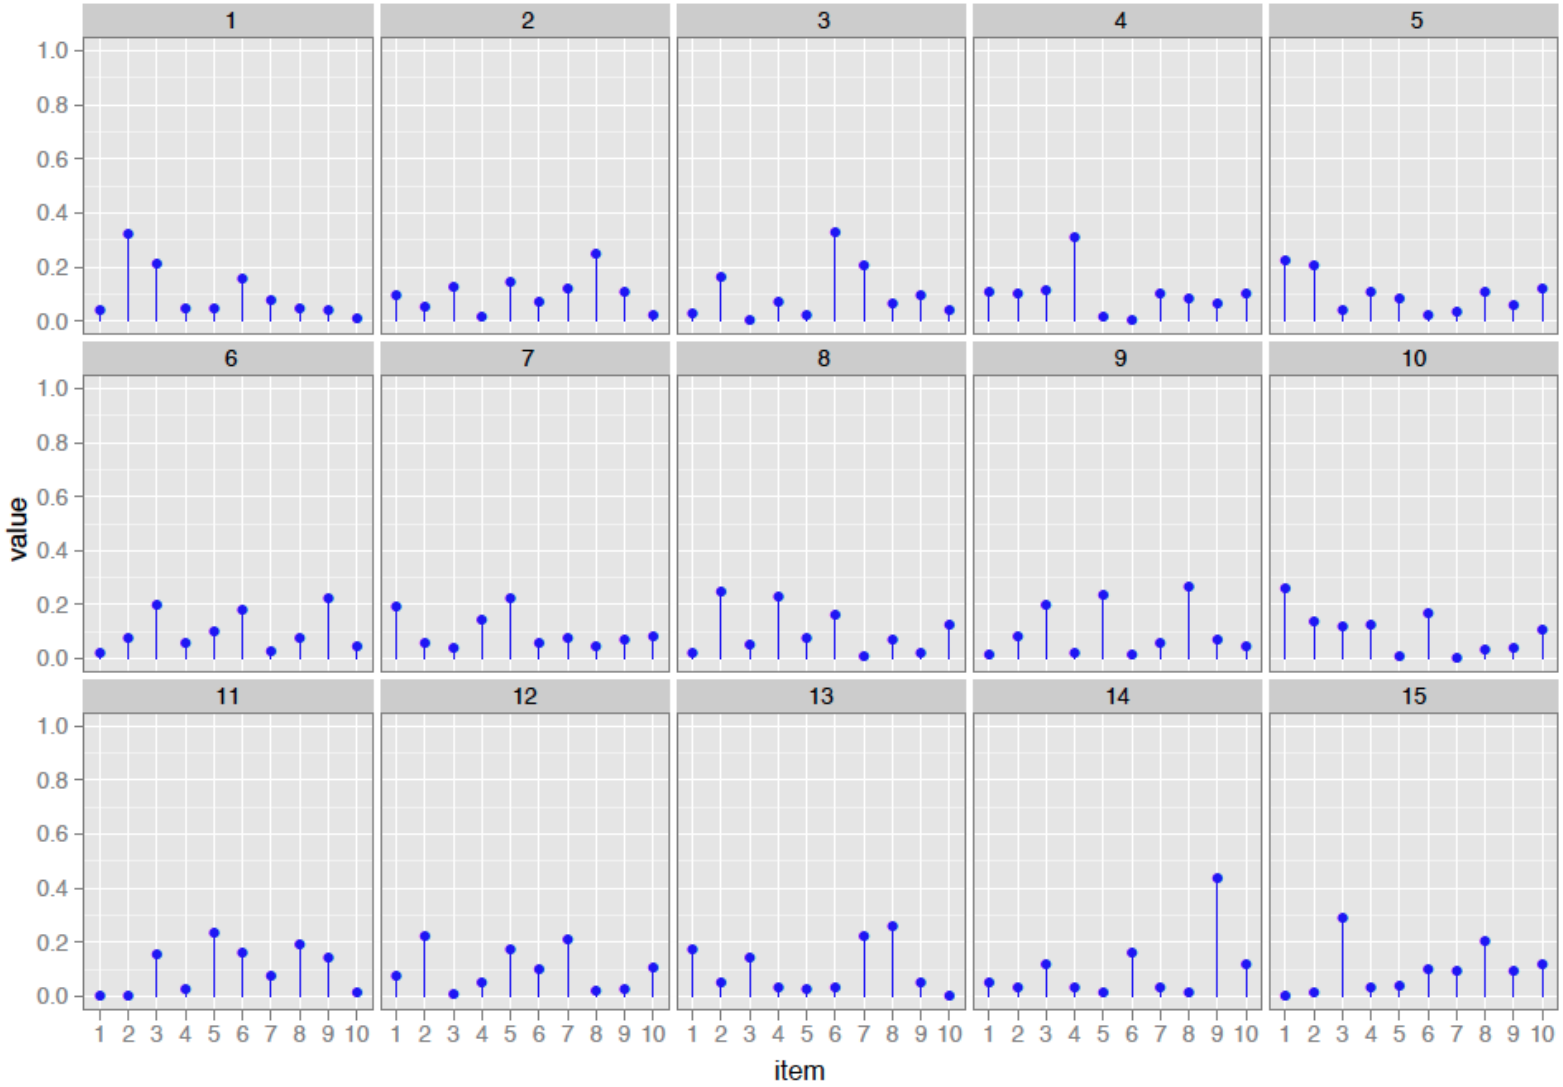
Dirichlet Distribution

$$p(\theta \mid \vec{\alpha}) = \frac{\Gamma\left(\sum_i \alpha_i\right)}{\prod_i \Gamma(\alpha_i)} \prod_i \theta_i^{\alpha_i - 1}$$

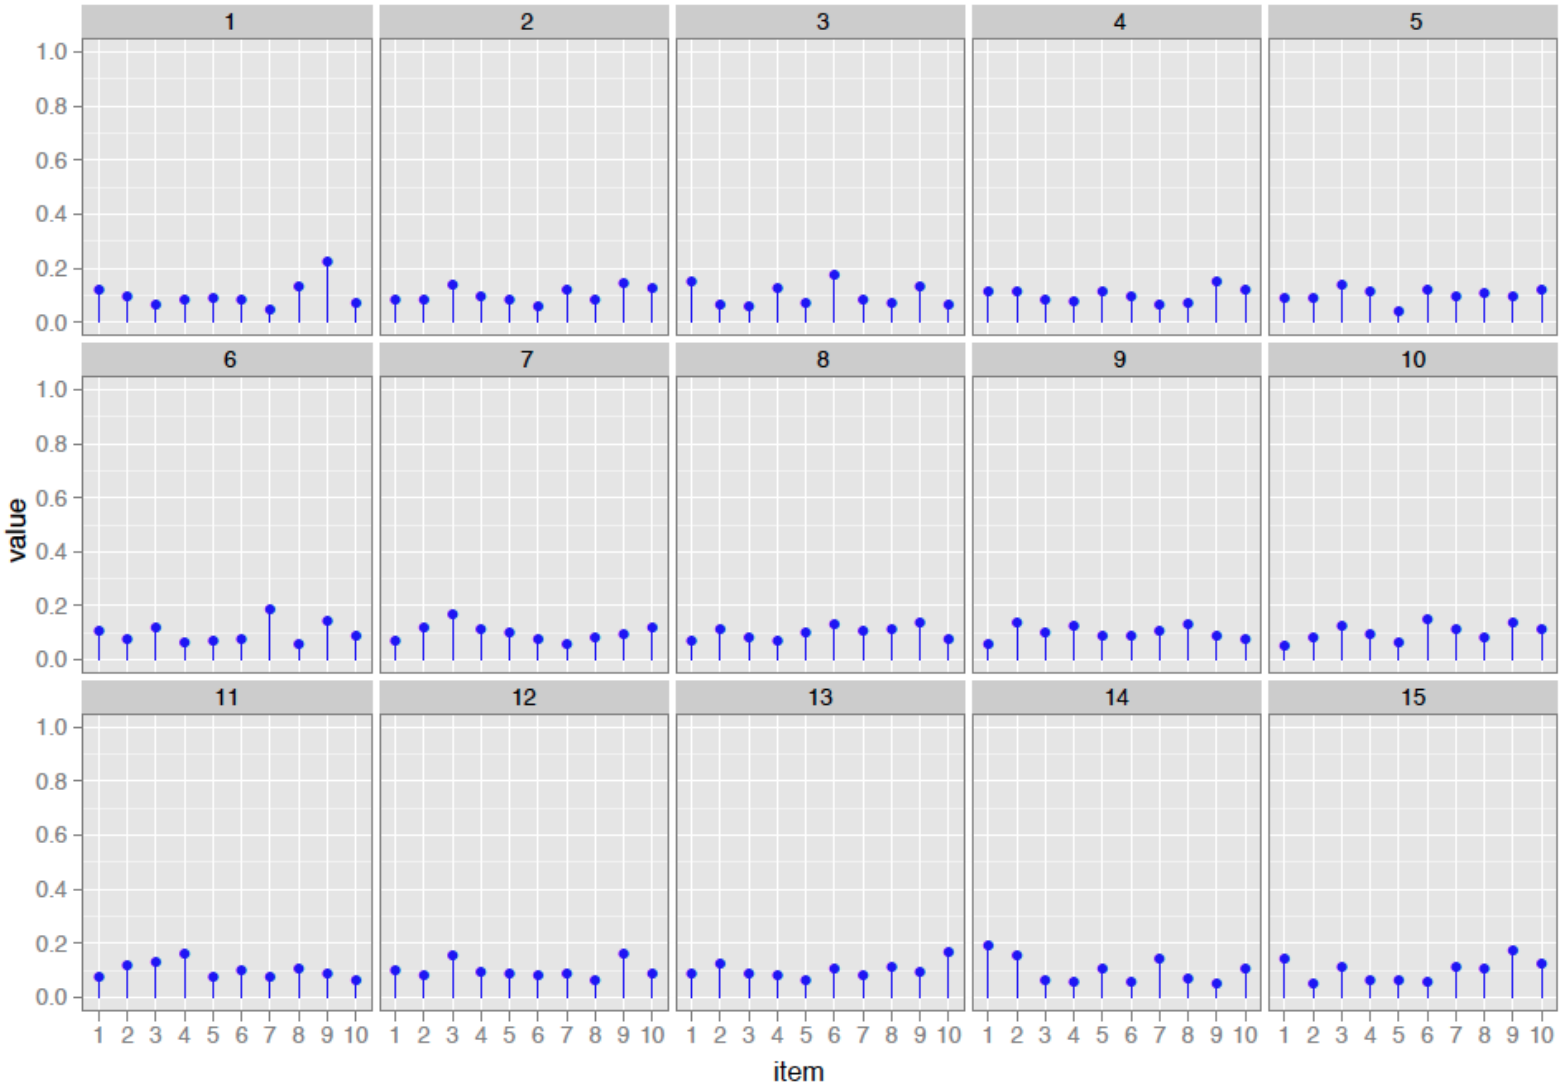


α_is: **hyper-parameters of the model which can be interpreted as:** It is convenient to use a symmetirc Dirichlet distribution with a single hyper-parameter $\alpha_1 = \alpha_2 \ldots = \alpha$

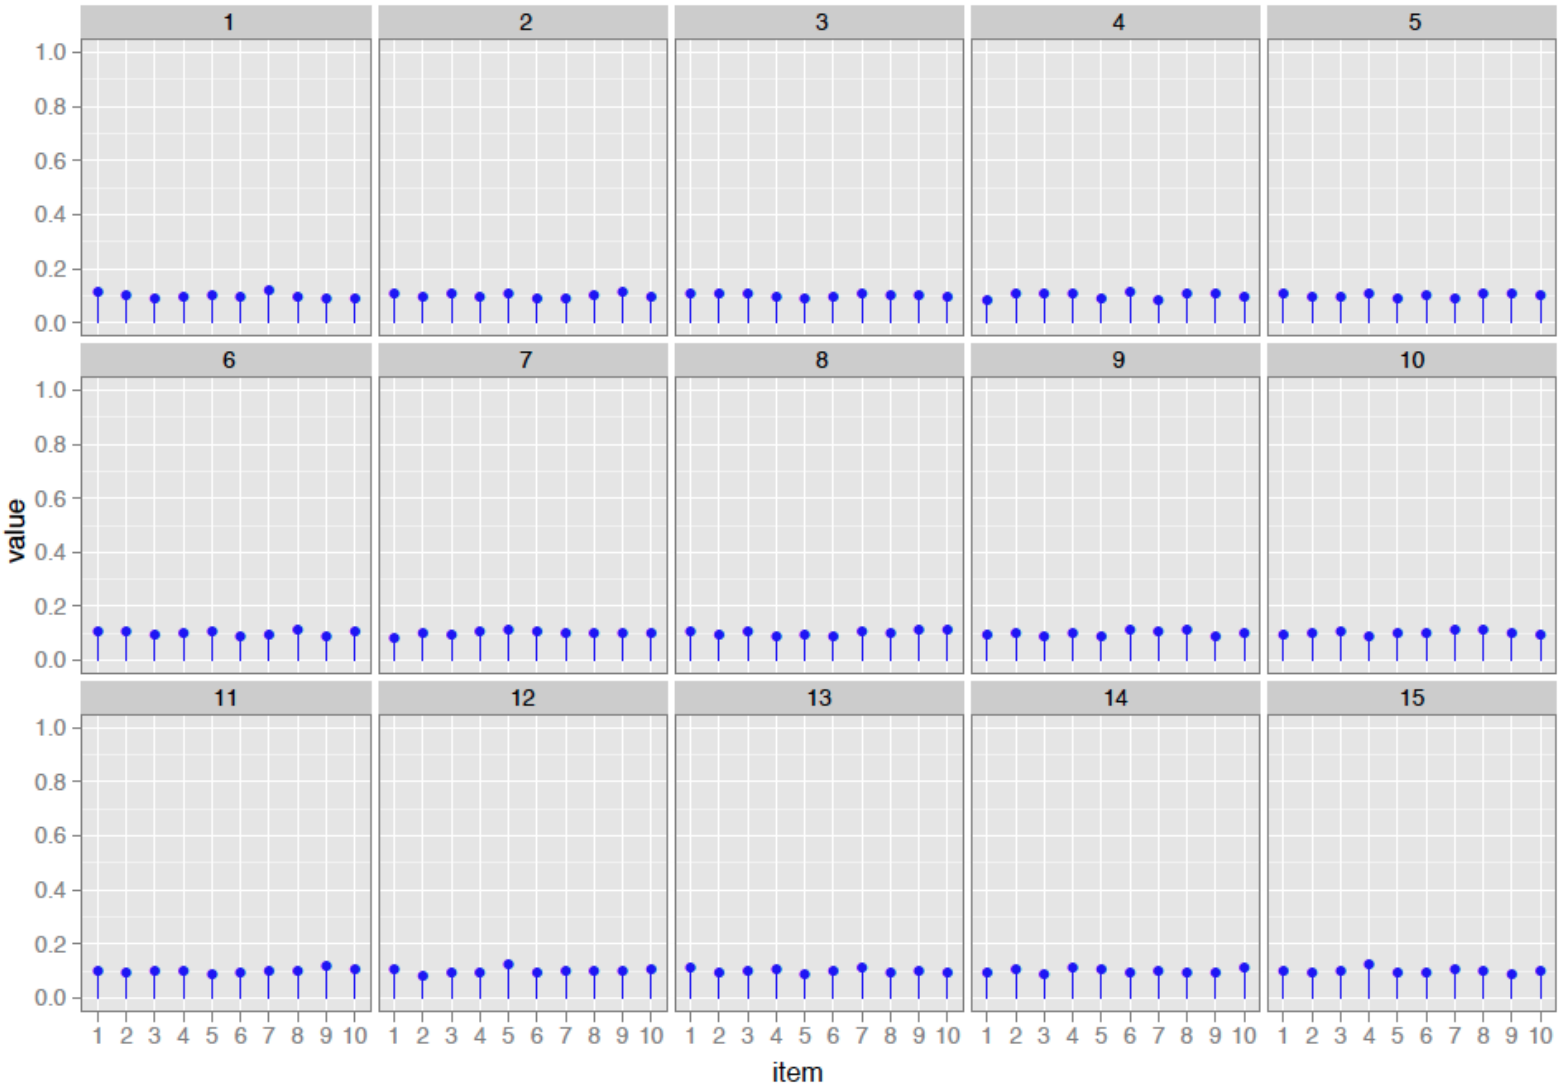
Effect of α: $\alpha = 1$



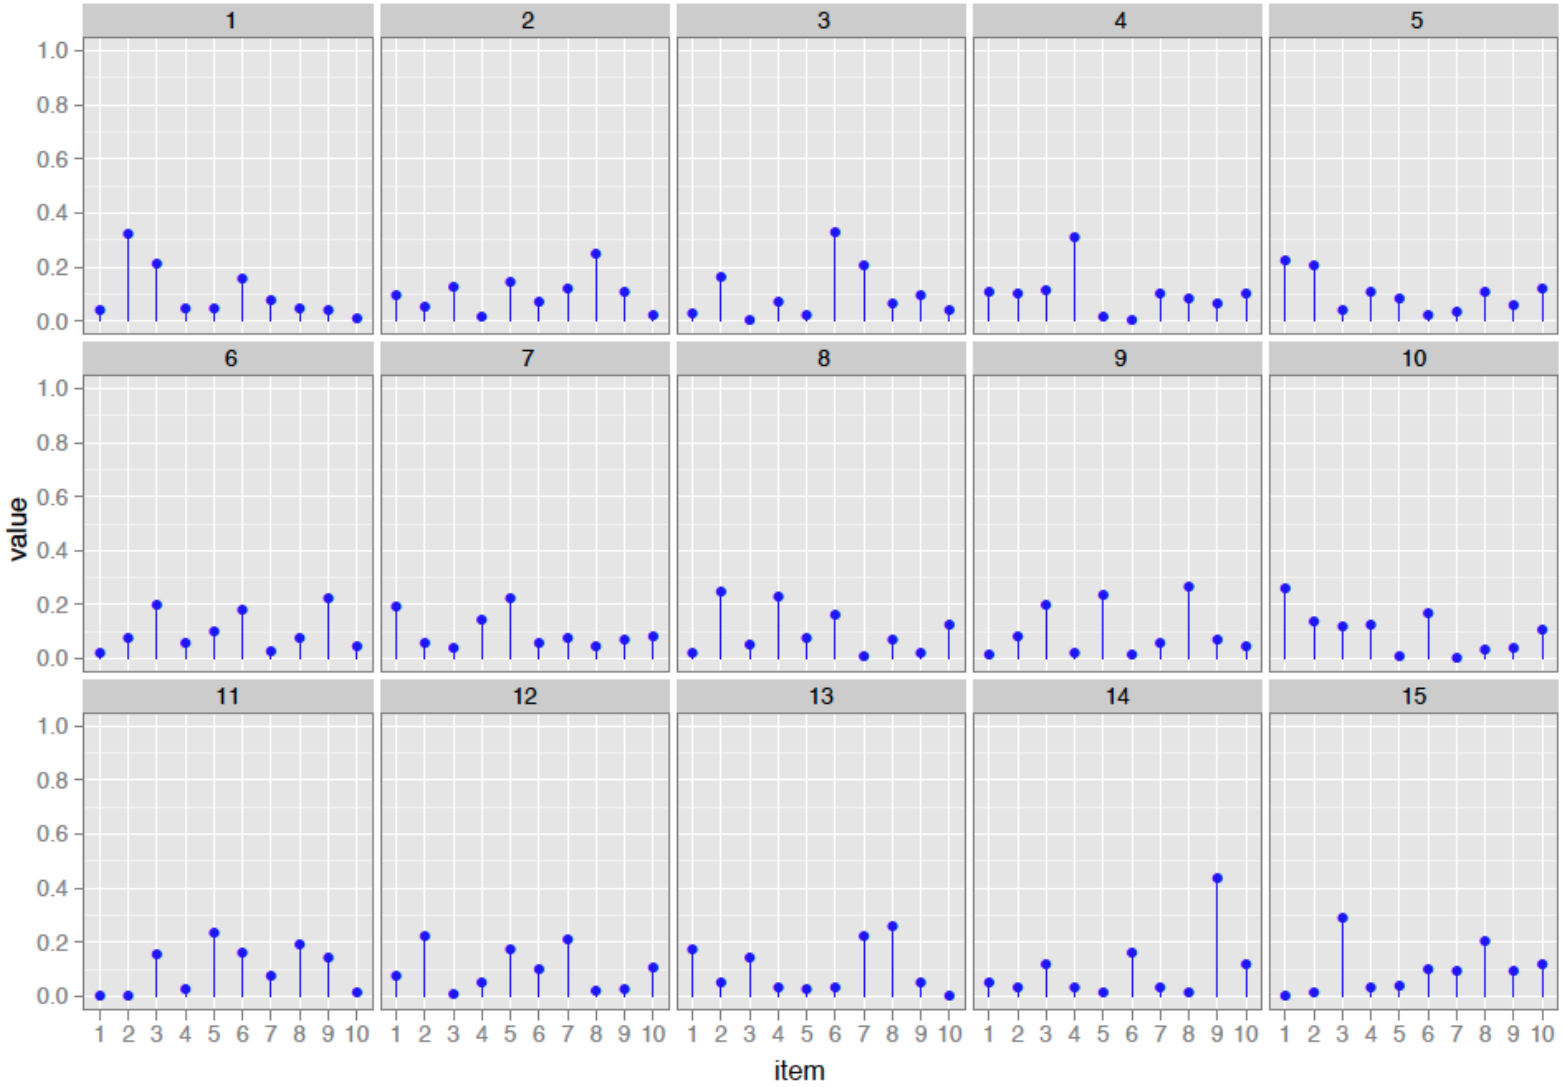
Effect of α: $\alpha = 10$



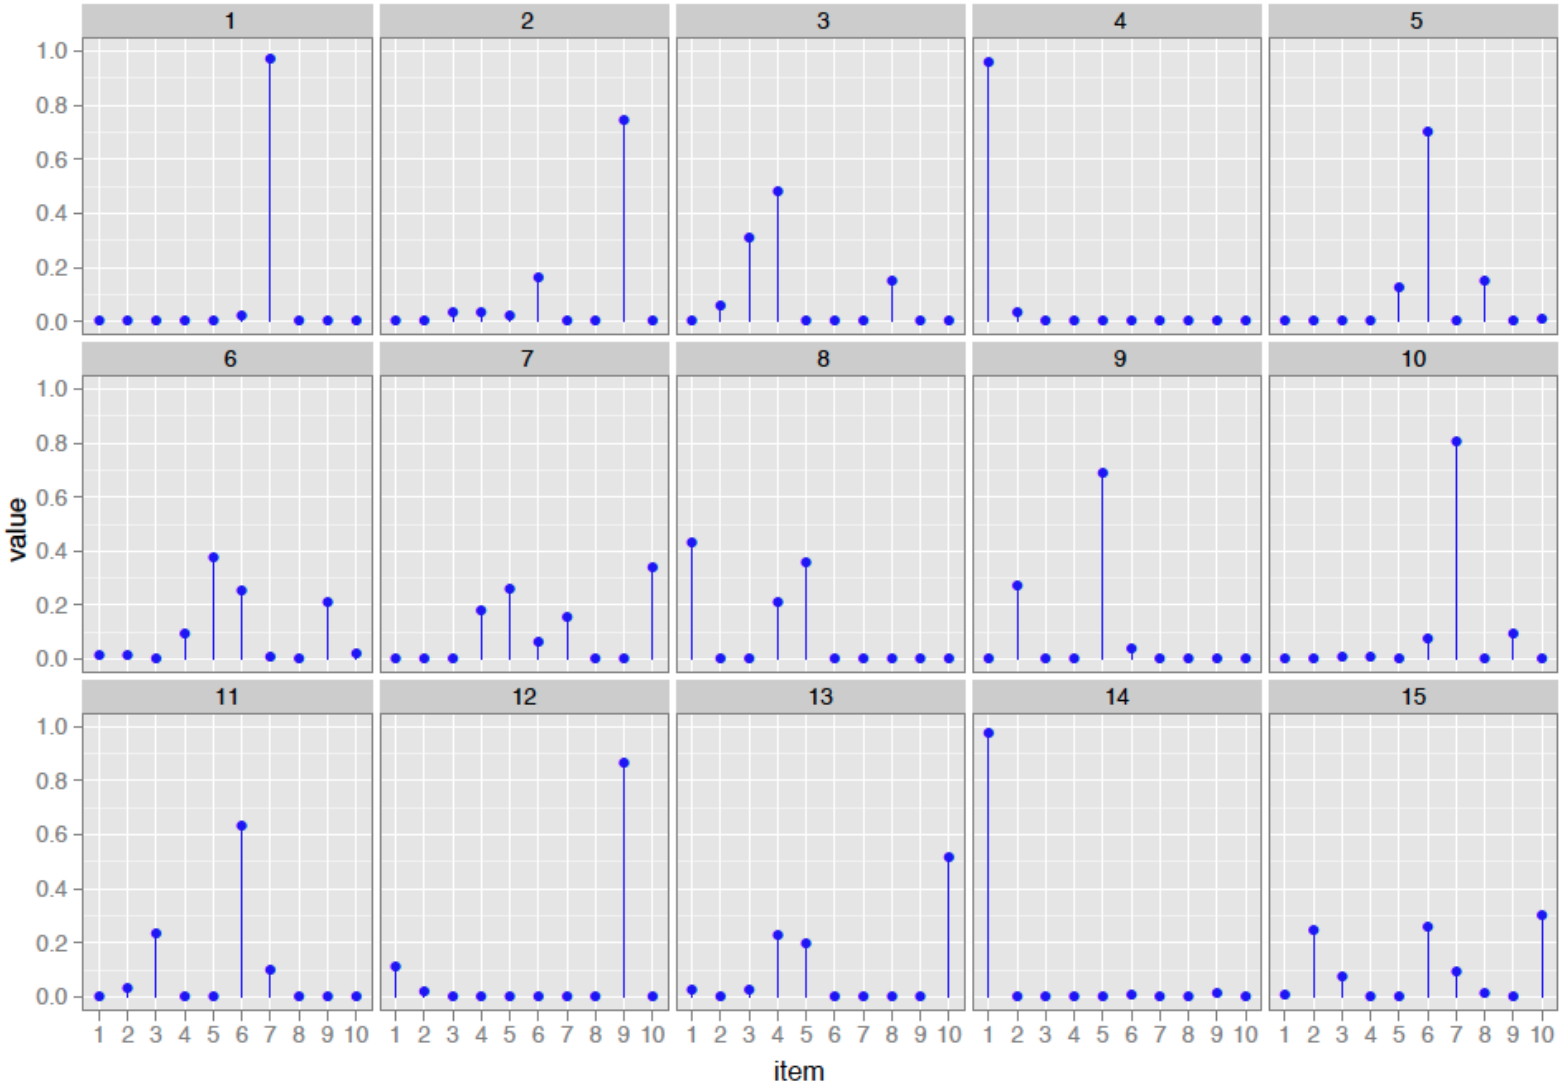
Effect of α: $\alpha = 100$



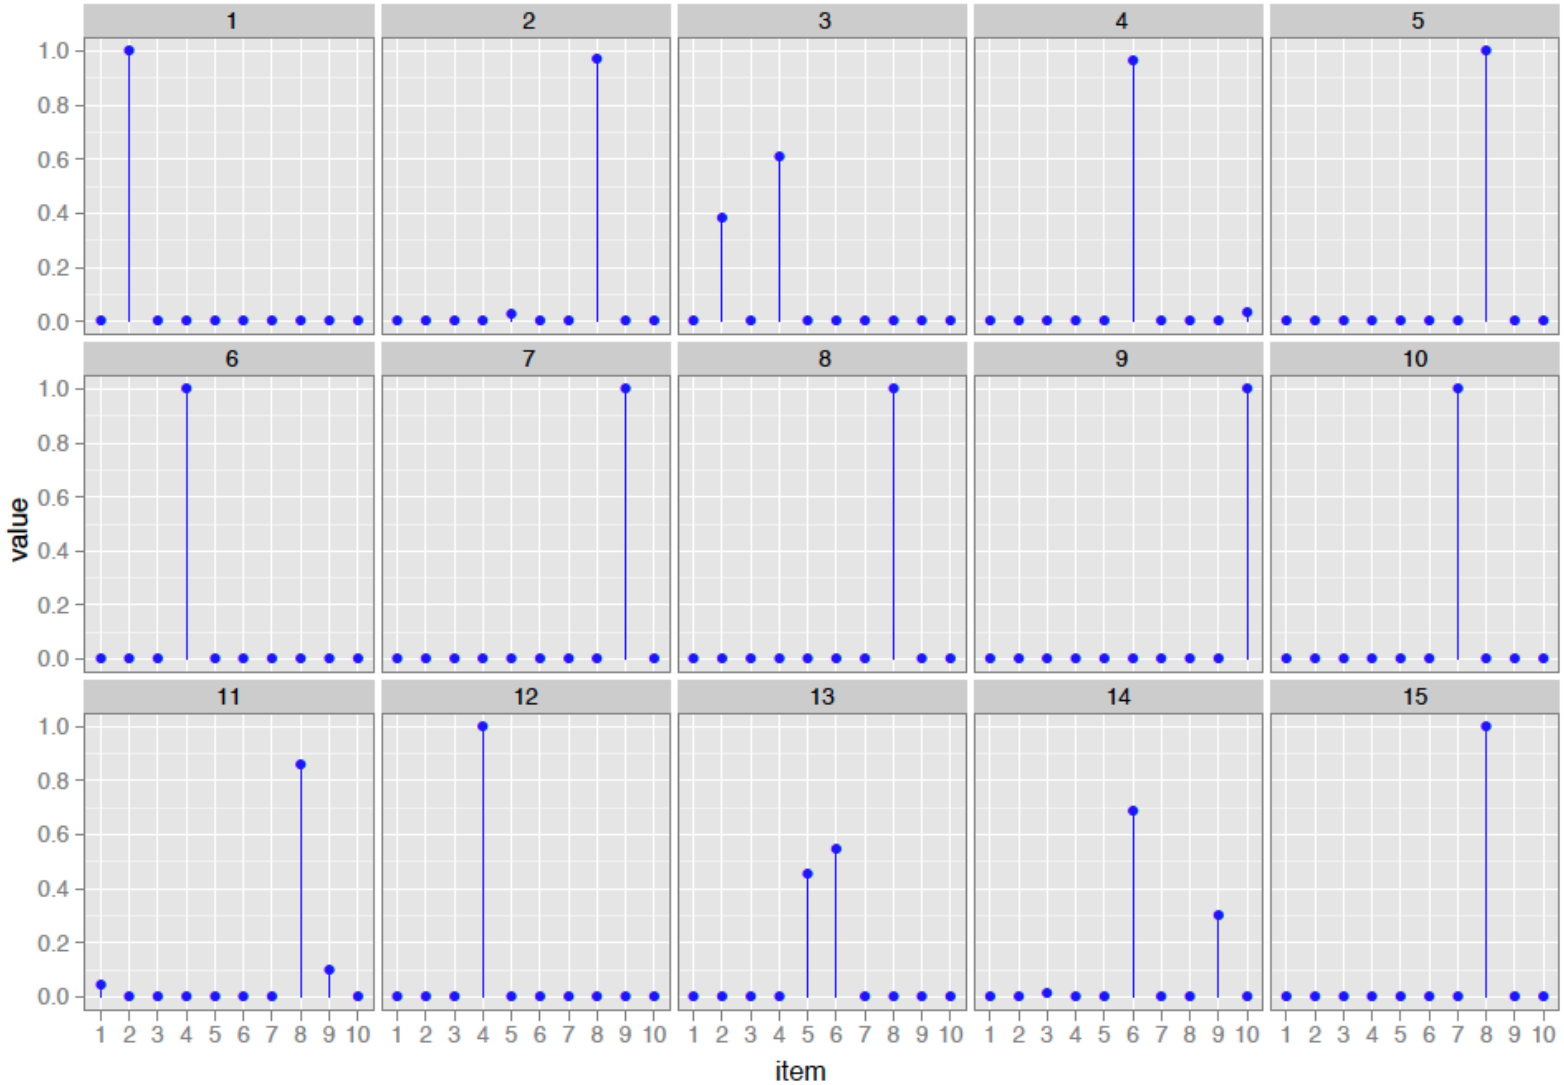
Effect of α: $\alpha = 1$



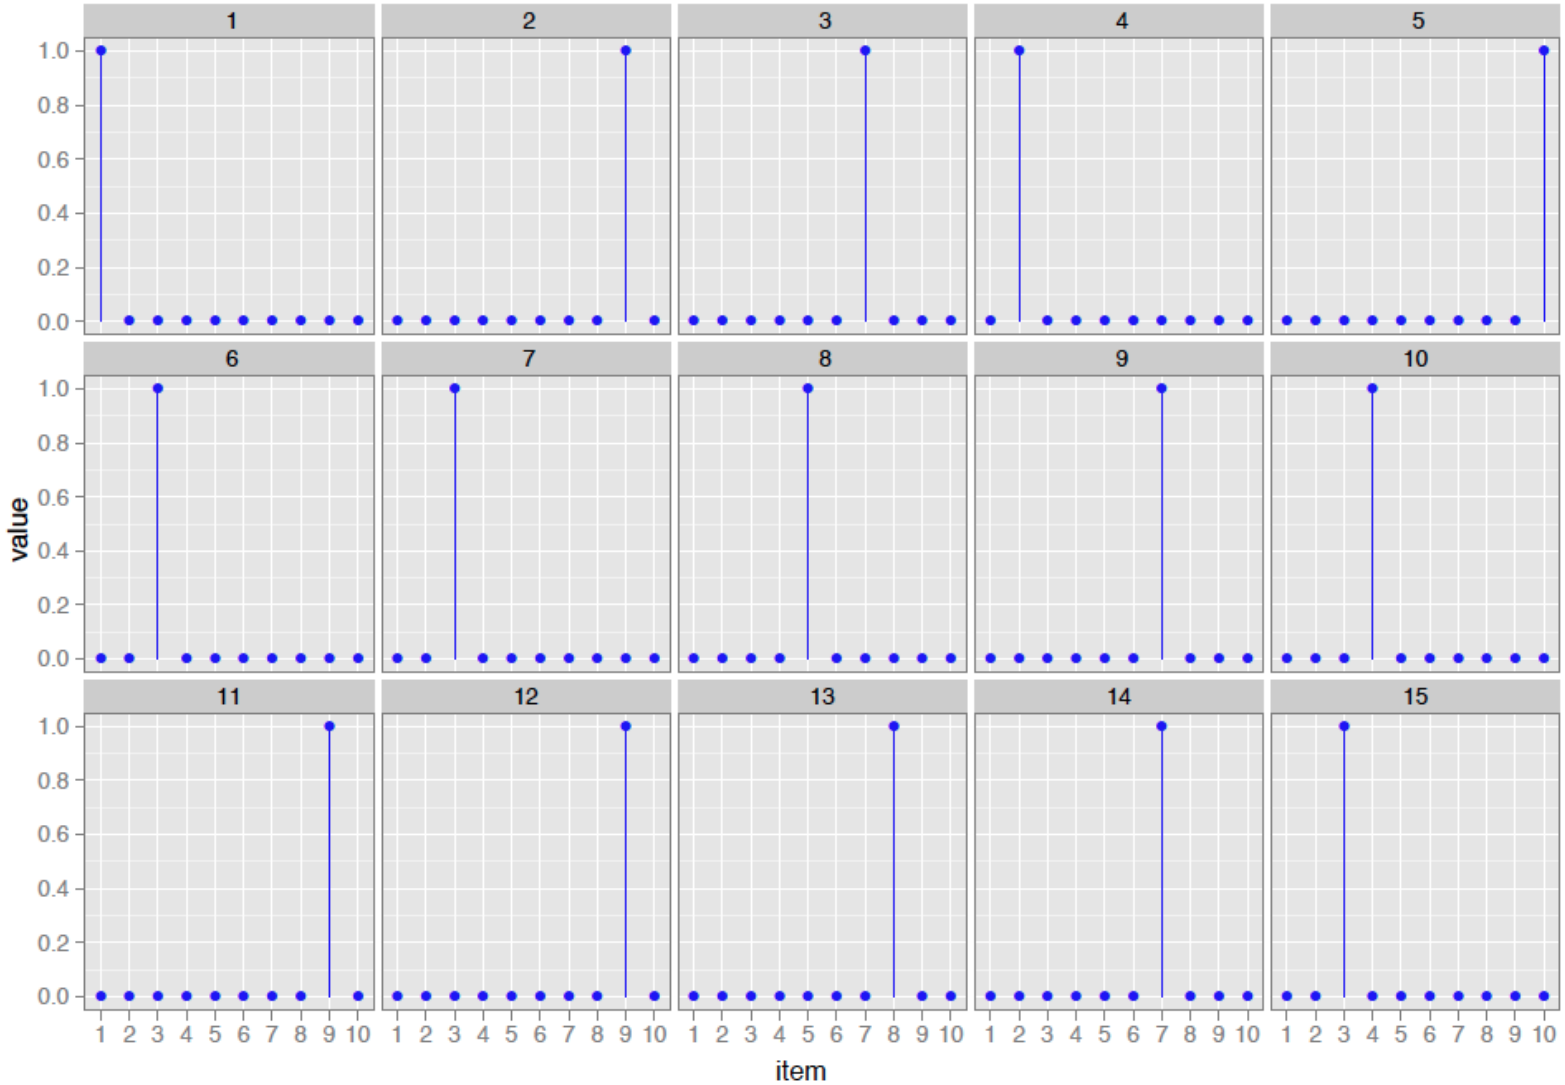
Effect of α: $\alpha = 0.1$



Effect of α: $\alpha = 0.01$



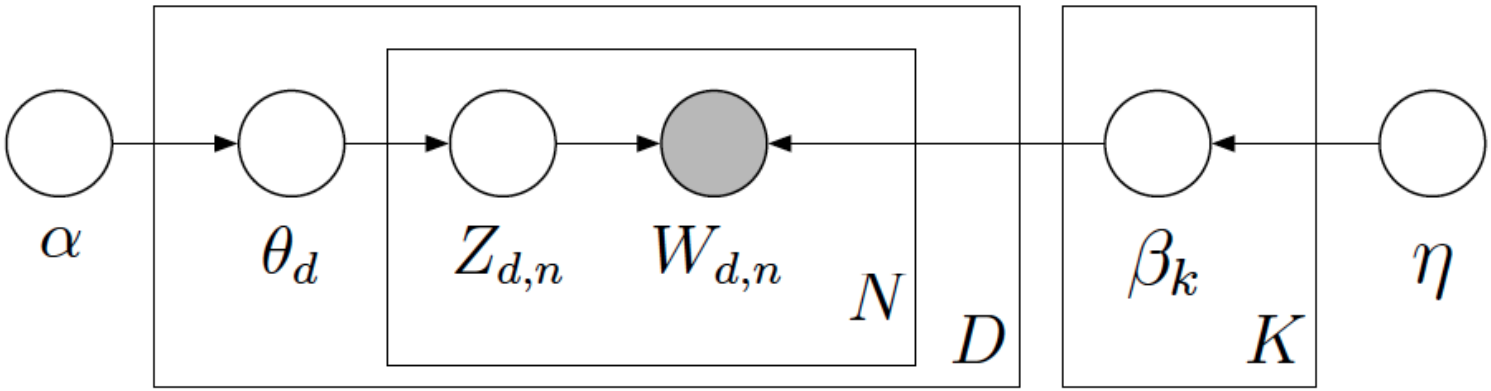
Effect of α: $\alpha = 0.001$



Online Implementations

LDA-C*	A C implementation of LDA
HDP*	A C implementation of the HDP ("infinite LDA")
Online LDA*	A python package for LDA on massive data
LDA in R*	Package in R for many topic models
LingPipe	Java toolkit for NLP and computational linguistics
Mallet	Java toolkit for statistical NLP
TMVE*	A python package to build browsers from topic models

Latent Dirichlet Allocation: Statistical Inference



- From a collection of documents, infer
  - Per-word topic assignment $z_{d,n}$
  - Per-document topic proportions θ_d
  - Per-corpus topic distributions β_k
- Use posterior expectations to perform the task at hand, e.g., information retrieval, document similarity, etc.

LDA: computing posterior

Joint distribution of the hidden and observed variables

$$p(\beta_{1:K}, \theta_{1:D}, z_{1:D}, w_{1:D})$$
$$= \prod_{i=1}^{K} p(\beta_i) \prod_{d=1}^{D} p(\theta_d)$$
$$\left(\prod_{n=1}^{N} p(z_{d,n} | \theta_d) p(w_{d,n} | \beta_{1:K}, z_{d,n}) \right)$$

LDA: computing posterior

Joint distribution of the hidden and observed variables

$$p(\beta_{1:K}, \theta_{1:D}, z_{1:D}, w_{1:D})$$
$$= \prod_{i=1}^{K} p(\beta_i) \prod_{d=1}^{D} p(\theta_d)$$
$$\left(\prod_{n=1}^{N} p(z_{d,n} | \theta_d) p(w_{d,n} | \beta_{1:K}, z_{d,n}) \right)$$

What is posterior?

Conditional distribution of the hidden variables given the observed variables

$$p(\beta_{1:K}, \theta_{1:D}, z_{1:D} | w_{1:D})$$
$$= \frac{p(\beta_{1:K}, \theta_{1:D}, z_{1:D}, w_{1:D})}{p(w_{1:D})}$$

Computing Posterior

$$p(\beta_{1:K}, \theta_{1:D}, z_{1:D} \mid w_{1:D}) = \frac{p(\beta_{1:K}, \theta_{1:D}, z_{1:D}, w_{1:D})}{p(w_{1:D})}$$

- Numerator is the joint distribution of all the random variables, which can be easily computed for any settings of the hidden variables
- Denominator is the *marginal probability* of the observations, probability of seeing the observed corpus under any topic model

Computing Posterior

$$p(\beta_{1:K}, \theta_{1:D}, z_{1:D} \mid w_{1:D}) = \frac{p(\beta_{1:K}, \theta_{1:D}, z_{1:D}, w_{1:D})}{p(w_{1:D})}$$

- Numerator is the joint distribution of all the random variables, which can be easily computed for any settings of the hidden variables
- Denominator is the *marginal probability* of the observations, probability of seeing the observed corpus under any topic model

This marginal is intractable to compute!

The sum is over all possible ways of assigning each observed word of the collection to one of the topics. Number of words can be of the order of millions!!

Can we approximate it?

Algorithms to approximate it fall in two categories:

Sampling-based Algorithms

Collect samples from the posterior to approximate it with an empirical distribution

Can we approximate it?

Algorithms to approximate it fall in two categories:

Sampling-based Algorithms

Collect samples from the posterior to approximate it with an empirical distribution

Variational Methods

- Deterministic alternative to sampling-based algorithms
- The inference problem is transformed to an optimization problem

Gibbs Sampling

- A form of Markov chain Monte Carlo (MCMC), which simulates a high-dimensional distribution by sampling on lower-dimensional subset of variables where each subset is conditioned on the value of all others
- Sampling is done sequentially and proceeds until the sampled values approximate the target distribution
- It directly estimates the posterior distribution over z , and uses this to provide estimates for β and θ

Gibbs Sampling

- Suppose we have a word token i for which we want to find the topic assignment probability : $p(z_i = j)$
- Represent the collection of documents by a set of word indices w_i and document indices d_i for this token i
- Gibbs sampling considers each word token in turn and estimates the probability of assigning the current word token to each topic, conditioned on the topic assignment to all other word tokens
- From this conditional distribution, a topic is sampled and stored as the new topic assignment for this word token
- This conditional is written as $P(z_i = j | z_{-i}, w_i, d_i, .)$

Gibbs Sampling

- Let us define two matrices C^{WT} and C^{DT} of dimensions $W \times T$ and $D \times T$ respectively.
- ${C_{wj}}^{WT}$ contains the number of times word w is assigned to topic j, not including the current instance
- ${C_{dj}}^{WT}$ contains the number of times topic j is assigned to some word token in document d, not including the current instance

Gibbs Sampling

- Let us define two matrices C^{WT} and C^{DT} of dimensions $W \times T$ and $D \times T$ respectively.
- ${C_{wj}}^{WT}$ contains the number of times word w is assigned to topic j, not including the current instance
- ${C_{dj}}^{WT}$ contains the number of times topic j is assigned to some word token in document d, not including the current instance

$$P(z_i = j | z_{-i}, w_i, d_i, .) \propto \frac{{C_{w_i j}}^{WT} + \eta}{\sum_{w=1}^{W} {C_{wj}}^{WT} + W\eta} \frac{{C_{d_i j}}^{DT} + \alpha}{\sum_{t=1}^{T} {C_{dj}}^{DT} + T\alpha}$$

- The left part is the probability of word w under topic j (How likely a word is for a topic) whereas
- the right part is the probability of topic j under the current topic distribution for document d (How dominant a topic is in a document)

Algorithm

- Start: Each word token is assigned to a random topic in $[1 \ldots T]$
- For each word token, a new topic is sampled as per $P(z_i = j | z_{-i}, w_i, d_i, .)$, adjusting the matrices C^{WT} and C^{DT}
- A single pass through all word tokens in the document is one *Gibbs sample*
- After the burnin period, these samples are saved at regularly spaced intervals, to prevent correlations between samples

Estimating θ and β

$$\beta_i^{(j)} = \frac{{C_{ij}}^{WT} + \eta}{\sum_{k=1}^{W} {C_{kj}}^{WT} + W\eta}$$

$$\theta_j^{(d)} = \frac{{C_{dj}}^{DT} + \alpha}{\sum_{k=1}^{T} {C_{dk}}^{DT} + T\alpha}$$

These values correspond to predictive distributions of

- sampling a new token of word i from topic j, and
- samping a new token in document d from topic j

An Example

The algorithm can be illustrated by generating artificial data from a known topic model and applying the algorithm to check whether it is able to infer the original genrative structure.

Example

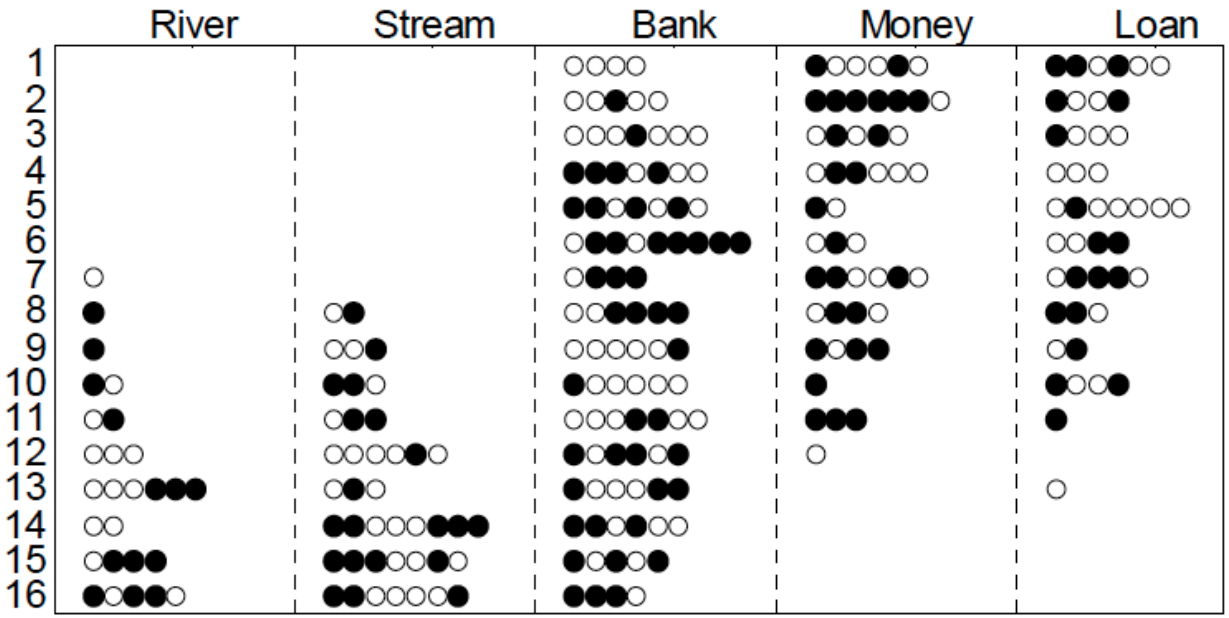
- Let topic 1 give equal probability to MONEY, LOAN, BANK and topic 2 give equal probability to words RIVER, STREAM, and BANK

$$\beta_{MONEY}^{(1)} = \beta_{LOAN}^{(1)} = \beta_{BANK}^{(1)} = 1/3$$

$$\beta_{RIVER}^{(2)} = \beta_{STREAM}^{(2)} = \beta_{BANK}^{(2)} = 1/3$$

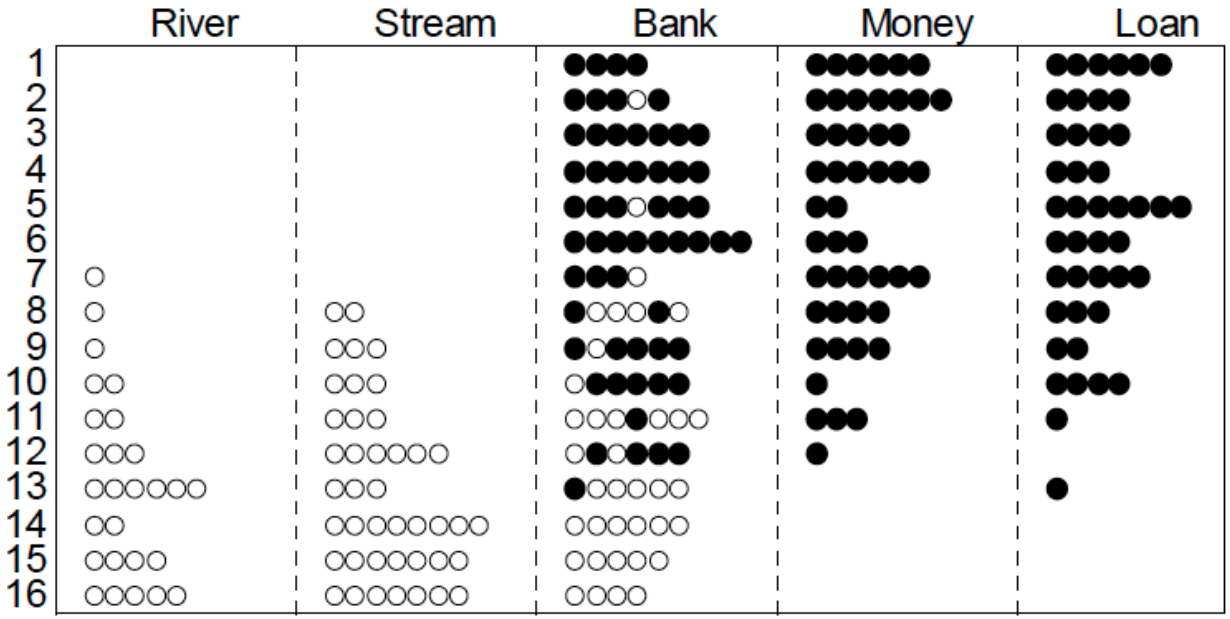
- We generate 16 documents by arbitrarily mixing two topics.

Initial Structure



Colors reflect initial random assignment, black = topic 1, while = topic 2

After 64 iterations of Gibbs Sampling



$$\beta_{MONEY}^{(1)} = 0.32, \beta_{LOAN}^{(1)} = 0.29, \beta_{BANK}^{(1)} = 0.39$$

$$\beta_{RIVER}^{(2)} = 0.25, \beta_{STREAM}^{(2)} = 0.4, \beta_{BANK}^{(2)} = 0.35$$

Computing Similarities

Document Similarity

Similarity between documents d_i and d_2 can be measured by the similarity between their topic distributions $\theta^{(d_1)}$ and $\theta^{(d_2)}$

KL divergence : $D(p,q) = \sum_{j=1}^{T} p_j log_2 \frac{p_j}{q_j}$

Symmetrized KL divergence: $\frac{1}{2}[D(p,q) + D(q,p)]$ seems to work well

Similarity with respect to query q

Maximize the conditional probability of query given the document:

$$p(q|d_i) = \prod_{w_k \in q} p(w_k|d_i)$$

$$= \prod_{w_k \in q} \sum_{j=1}^{T} P(w_k|z=j)P(z=j|d_i)$$

Computing Similarities

Similarity between two words

Having observed a single word in a new context, what are the other words that might appear in the same context, based on the topic interpretation for the observed word?

$$p(w_2|w_1) = \sum_{j=1}^{T} p(w_2|z=j)p(z=j|w_i)$$

Example

Observed and predicted responses for the word 'PLAY'

Seeking Life's Bare (Genetic) Necessities

COLD SPRING HARBOR, NEW YORK—How many genes does an organism need to survive? Last week at the genome meeting here,* two genome researchers with radically different approaches presented complementary views of the basic genes needed for life. One research team, using computer analyses to compare known genomes, concluded that today's organisms can be sustained with just 250 genes, and that the earliest life forms required a mere 128 genes. The other researcher mapped genes in a simple parasite and estimated that for this organism, 800 genes are plenty to do the job—but that anything short of 100 wouldn't be enough.

Although the numbers don't match precisely, those predictions "are not all that far apart," especially in comparison to the 75,000 genes in the human genome, notes Siv Andersson of Uppsala University in Sweden, who arrived at the 800 number. But coming up with a consensus answer may be more than just a genetic numbers game, particularly as more and more genomes are completely mapped and sequenced. "It may be a way of organizing any newly sequenced genome," explains Arcady Mushegian, a computational molecular biologist at the National Center for Biotechnology Information (NCBI) in Bethesda, Maryland. Comparing an

Modeling Richer Assumptions in Topic Models

- Correlated topic models
- Dynamic topic models
- Measuring scholarly impact

Correlated Topic Models

- The Dirichlet is an exponential family distribution on the simplex, positive vectors that sum to one
- However, the near independence of components makes it a poor choice for modeling topic proportions
- An article about *fossil fuels* is more likely to also be about *geology* than about *genetics*

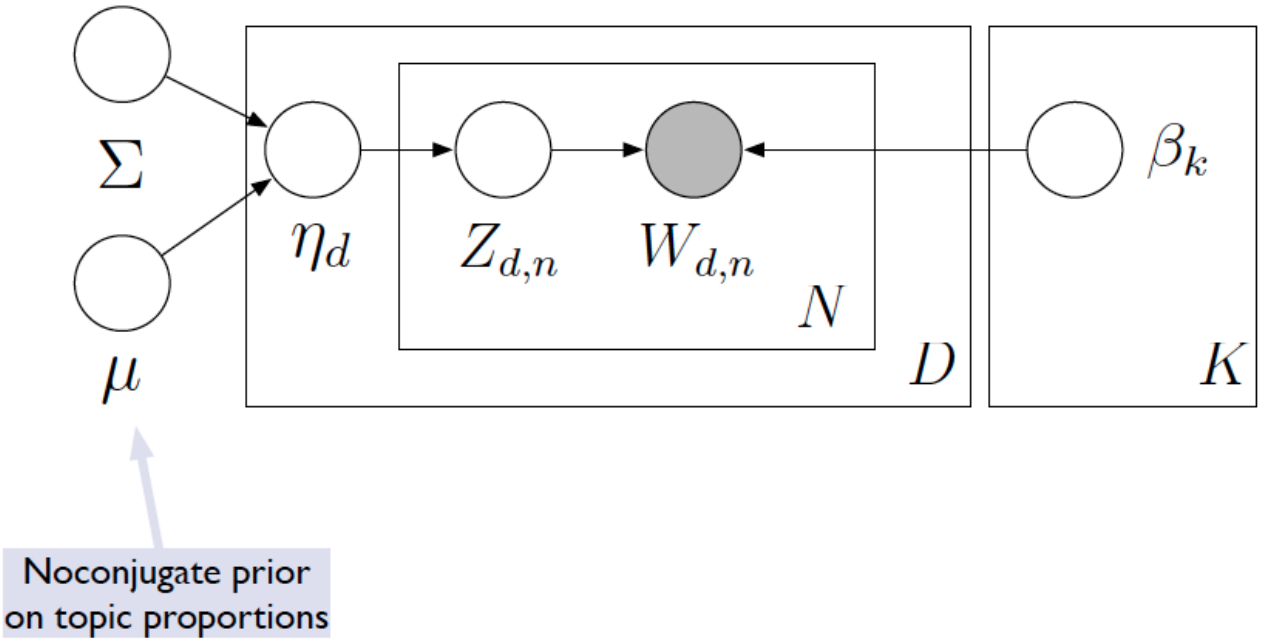
Using logistic normal distribution

A multivariate normal distribution of a k-dimensional vector $x = [X_1, X_2, \ldots, X_k]$ can be written as

$$x \sim N_k(\mu, \Sigma)$$

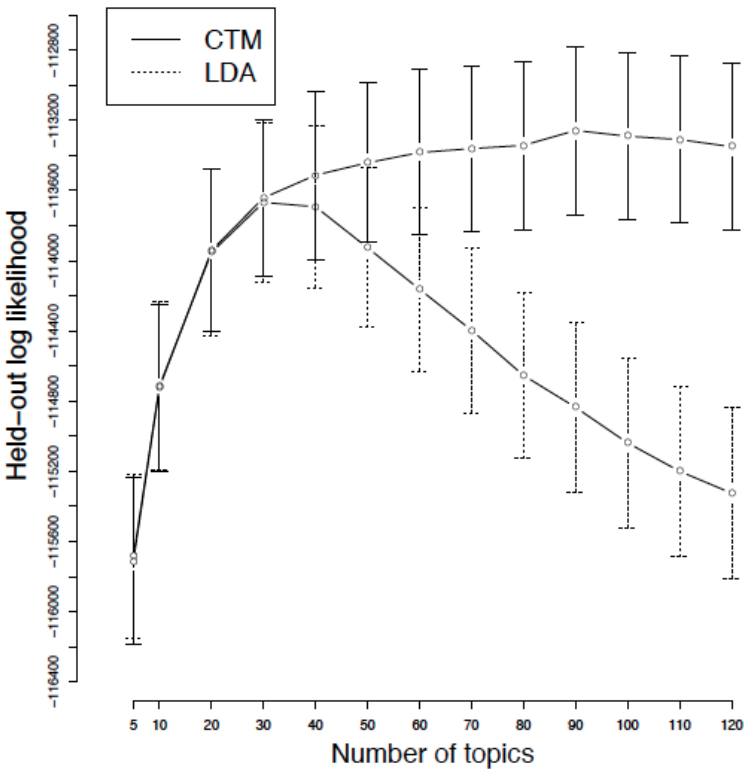
with k-dimensional mean vector μ and $k \times k$ covariance matrix Σ

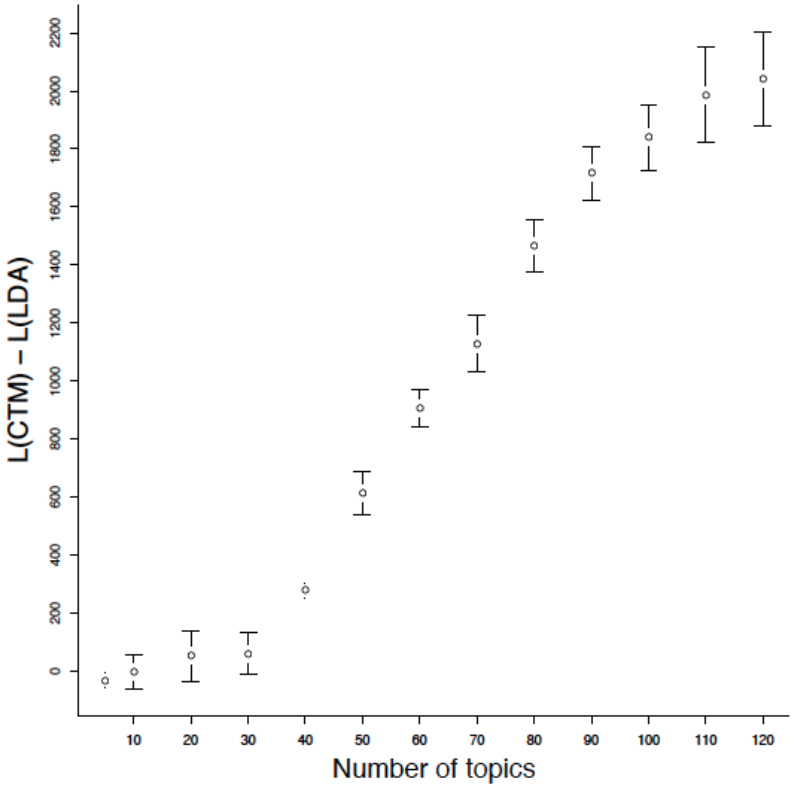
Correlated Topic Model (CTM)



- Draw topic proportions from a logistic normal, where topic occurrences can exhibit correlation.
- Use for:
  - Providing a "map" of topics and how they are related
  - Better prediction via correlated topics

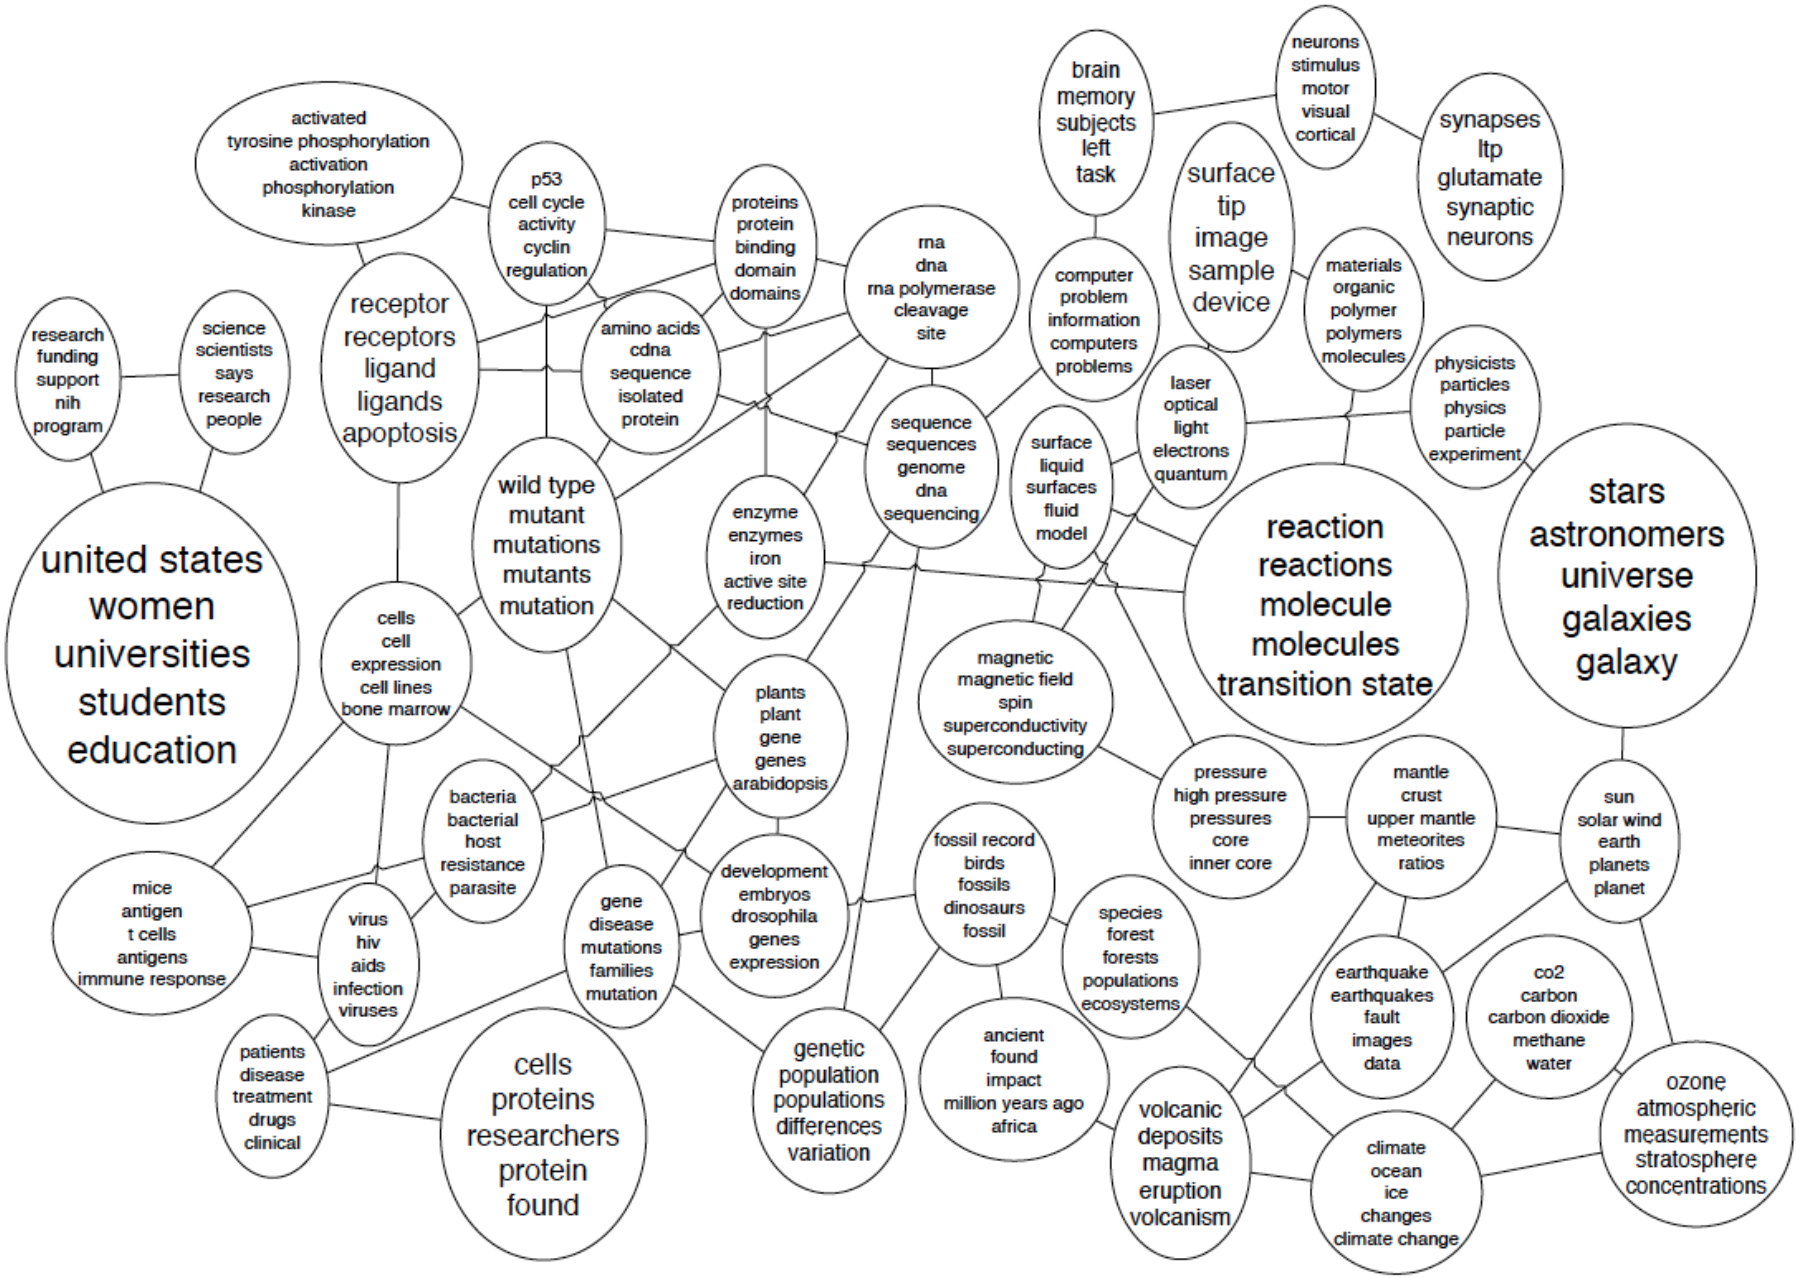
CTM supports more topics and provides a better fit than LDA





Held-out log probability on *Science*

Correlated Topics

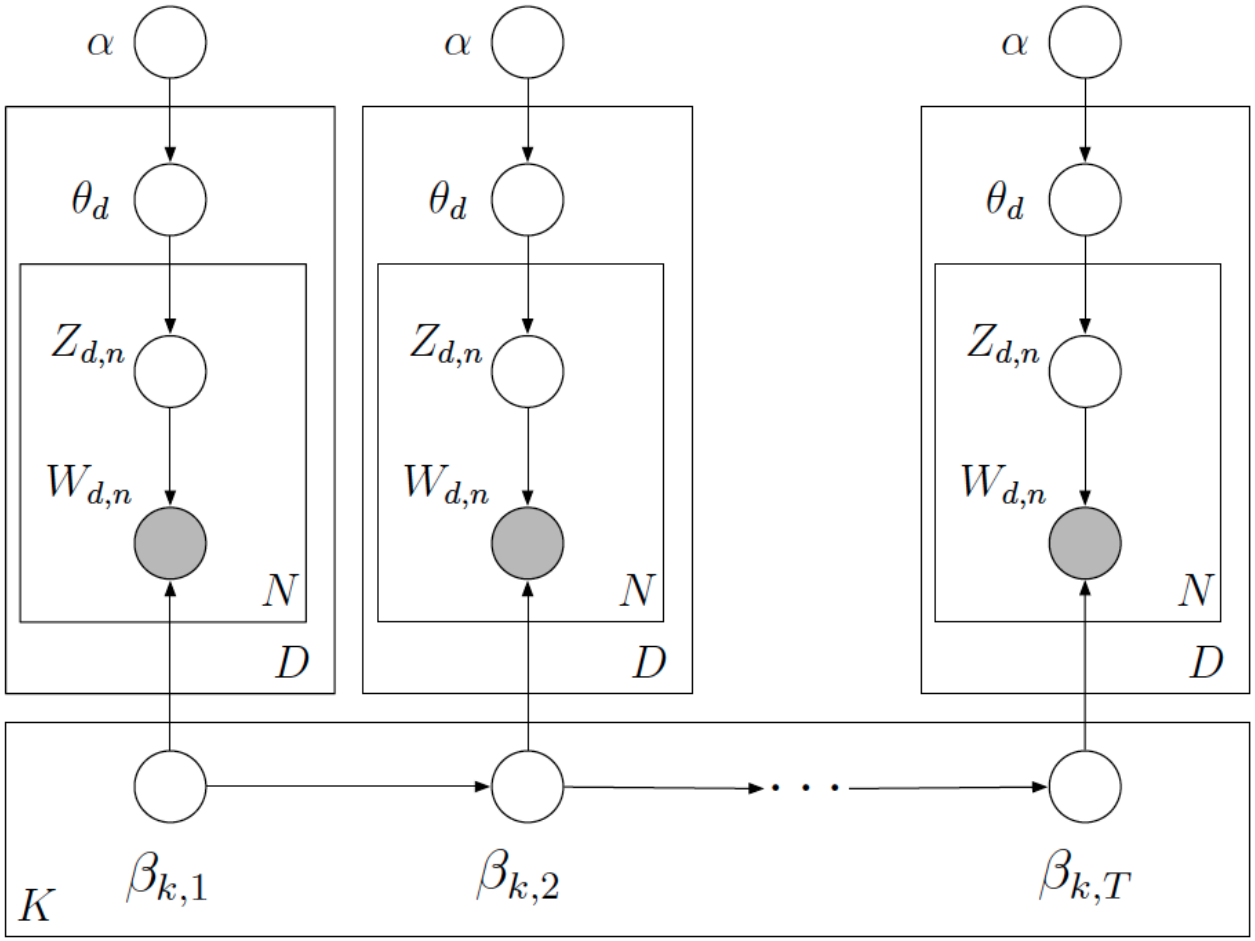


Dynamic Topic Models

LDA assumption

- LDA assumes that the order of documents does not matter
- Not appropriate for corpora that span hundreds of years
- We might want to track how language changes over time

Dynamic Topic Models



$$\beta_{k,t}|\beta_{k,t-1} \sim N(\beta_{k,t-1}, \sigma^2 I)$$

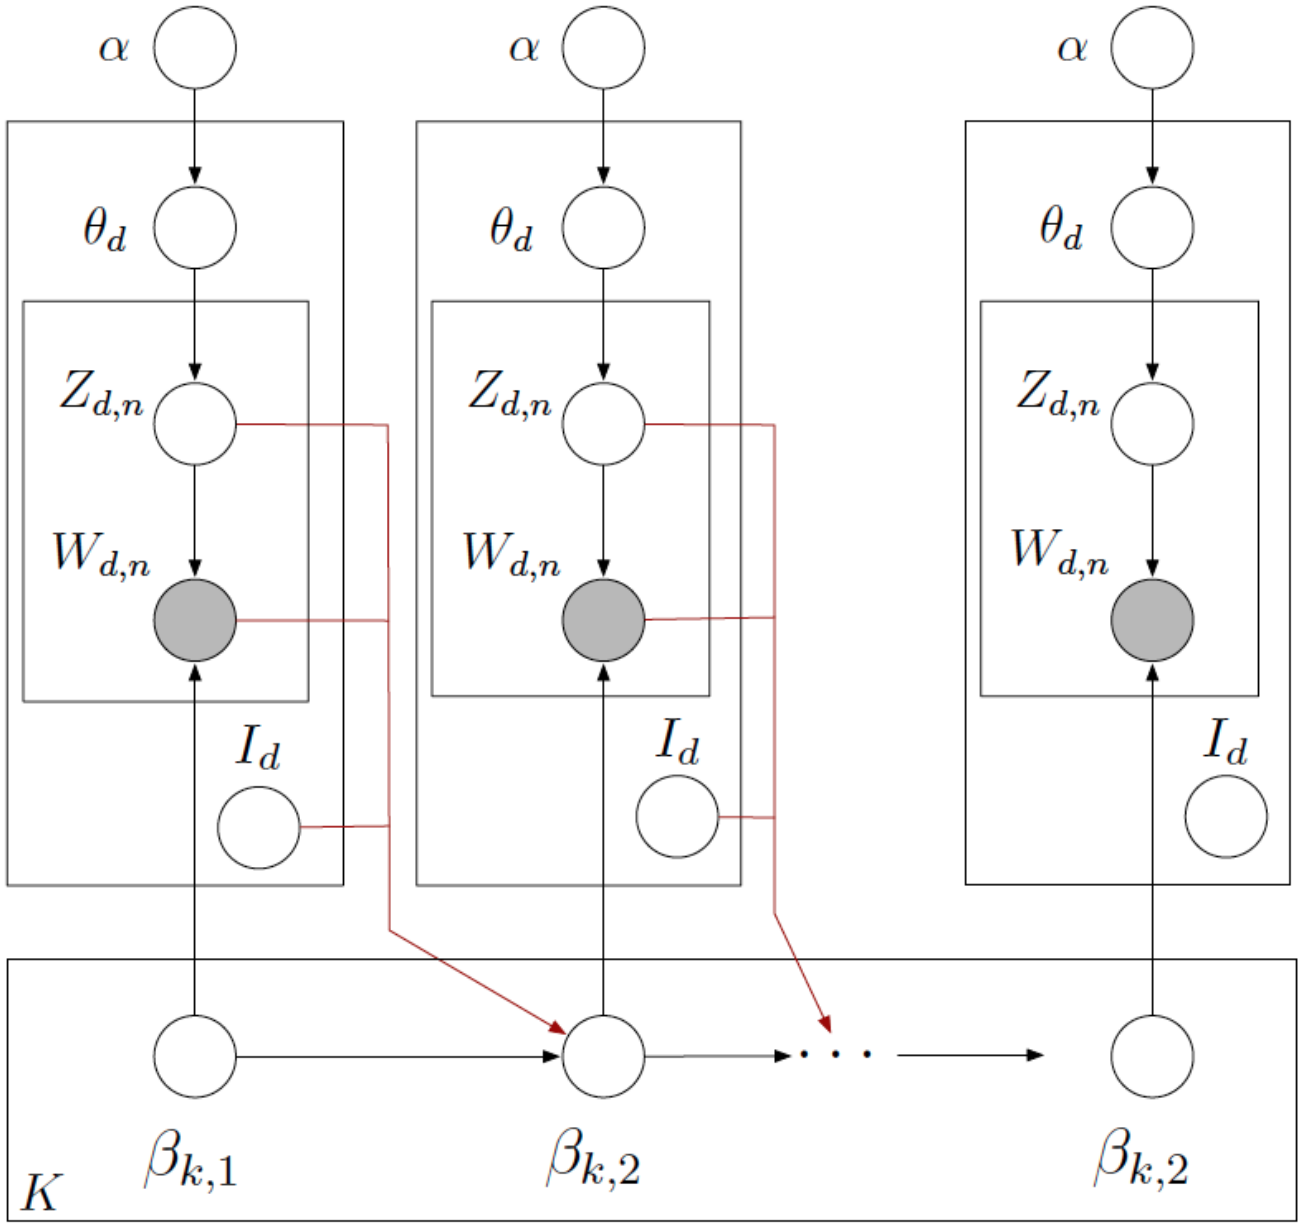
Measuring Scholarly Impact

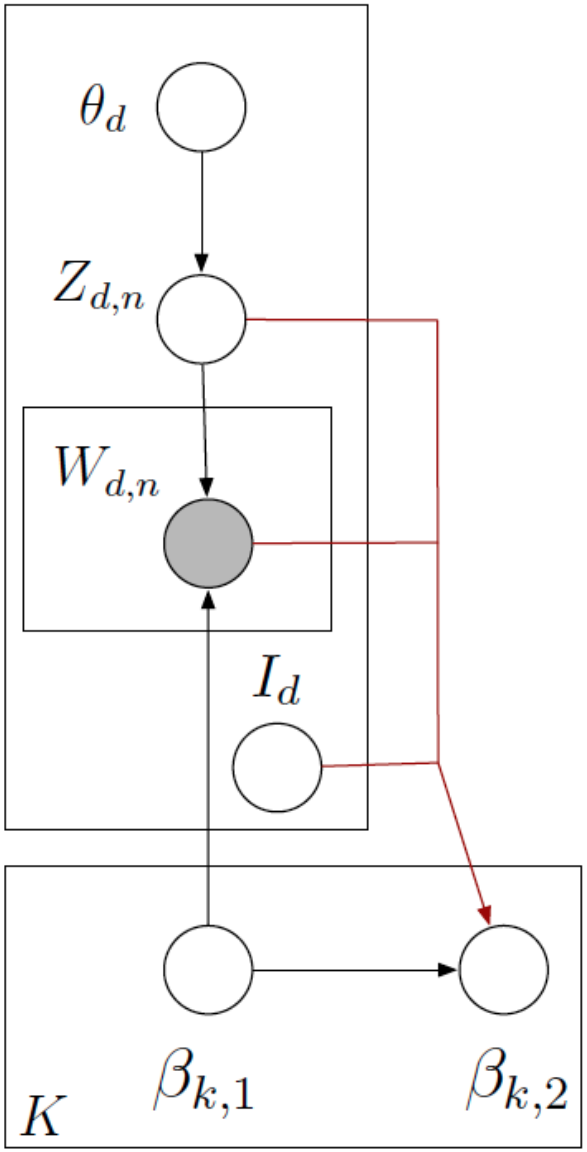
How to model influence?

- *Idea from Dynamic Topic Models*, influential articles reflect future changes in language use
- The *influence* of an article is a latent variable
- Inflential articles affect the drift of the topics that they discuss
- The posterior gives a retrospective estimate of influential article

Measuring Scholarly Impact

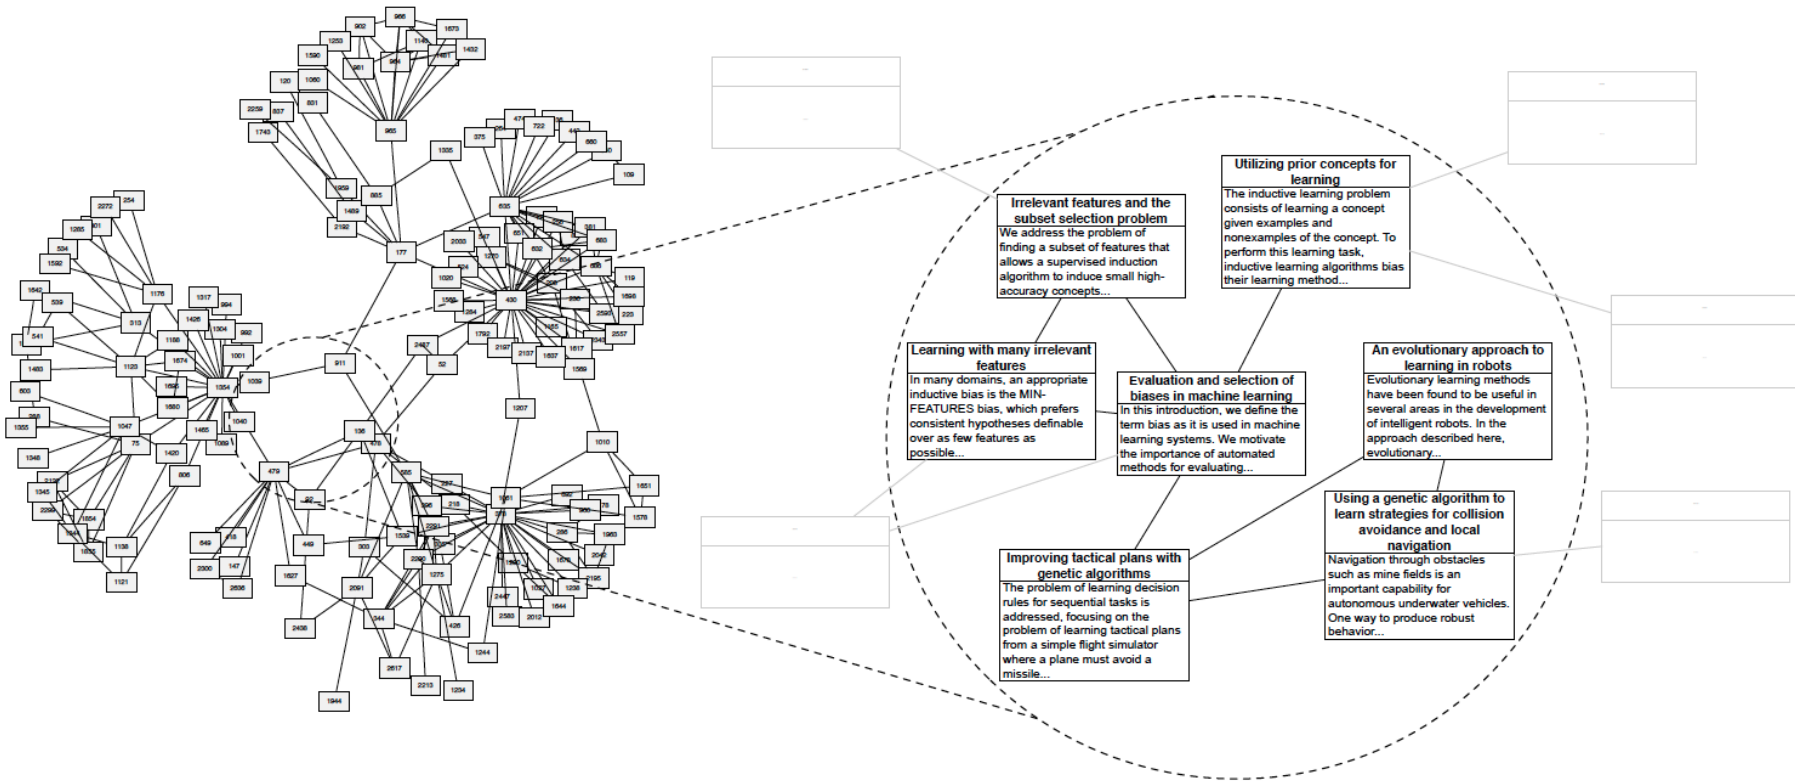


Measuring Scholarly Impact



- Each document has an influence score I_d.
- Each topic drifts in a way that is biased towards the documents with high influence.
- The posterior of $I_{1:D}$ can be examined to retrospectively find articles that best explain future changes in language.

Relational Topic Models



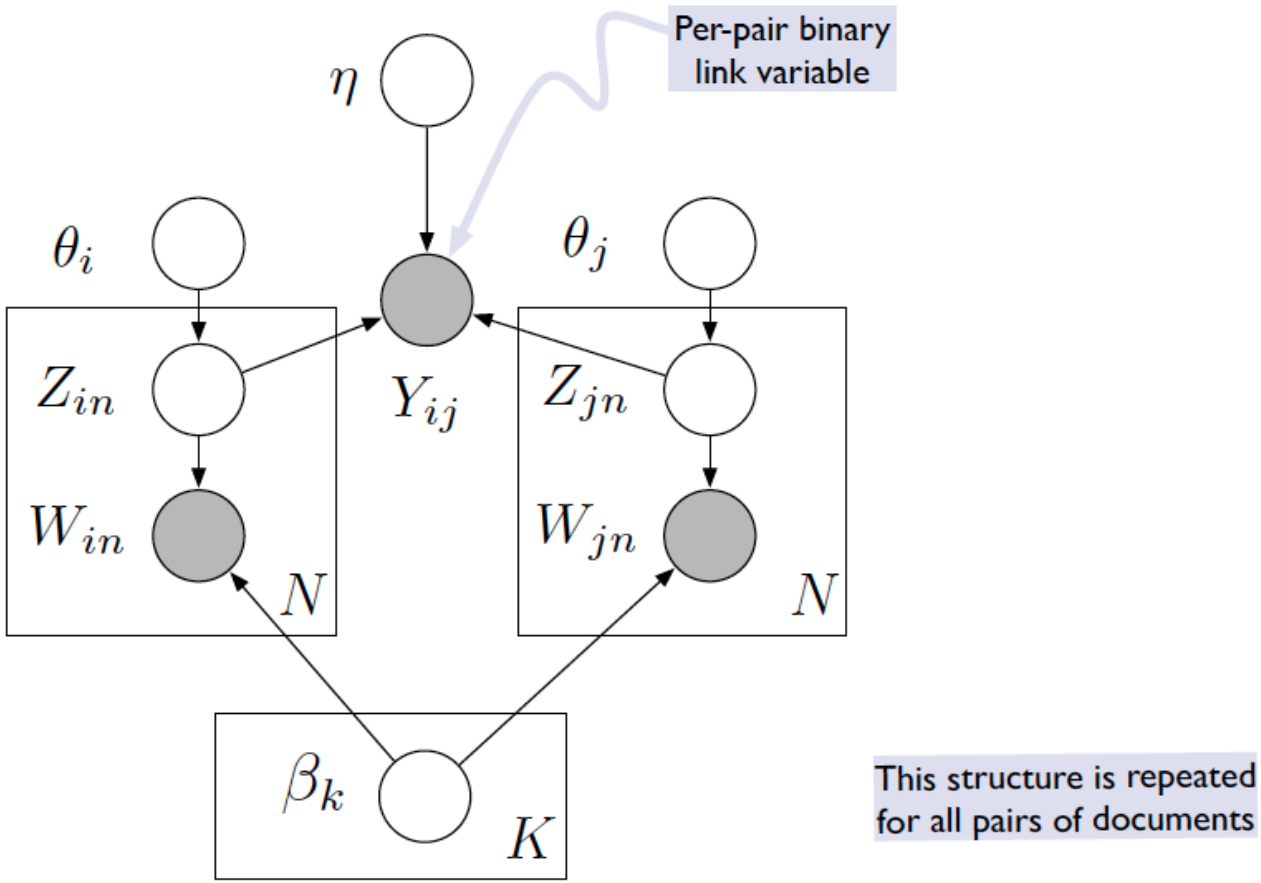
Connected Observations

- Citation networks of documents
- Hyperlinked networks of web-pages
- Friend-connected social network profiles

Relational Topic Models

- LDA needs to be adapted to a model of content and connection
- RTMs find hidden structure in both types of data

Relational Topic Models



Works in a supervised framework, allowing predictions about new and unlinked data

Link Prediction Task using RTM

Given a new document, which documents is it likely to link to?

Markov chain Monte Carlo convergence diagnostics: A comparative review
Minorization conditions and convergence rates for Markov chain Monte Carlo
Rates of convergence of the Hastings and Metropolis algorithms
Possible biases induced by MCMC convergence diagnostics
Bounding convergence time of the Gibbs sampler in Bayesian image restoration
Self regenerative Markov chain Monte Carlo
Auxiliary variable methods for Markov chain Monte Carlo with applications
Rate of Convergence of the Gibbs Sampler by Gaussian Approximation
Diagnosing convergence of Markov chain Monte Carlo algorithms

RTM allows for such predictions

- links given the new words of a document
- words given the links of a new document

Supervised settings of LDA

Use data points paired with response variables

- User reviews paired with a number of stars
- Web pages paired with a number of likes
- Documents paired with links to other documents
- Images paired with a category

Supervised settings of LDA

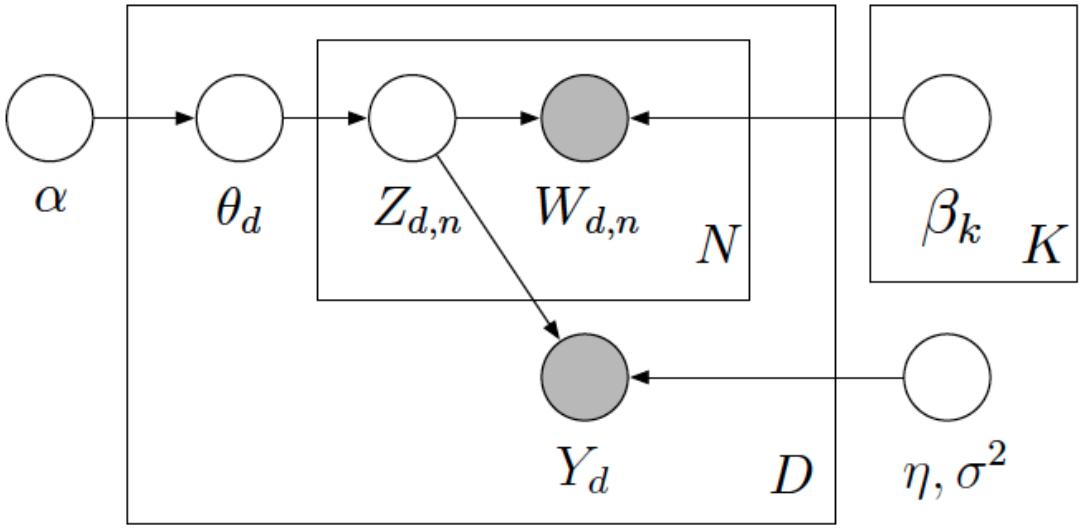
Use data points paired with response variables

- User reviews paired with a number of stars
- Web pages paired with a number of likes
- Documents paired with links to other documents
- Images paired with a category

Supervised topic modes

are topic models of documents and responses, fit to find topics predictive of the response

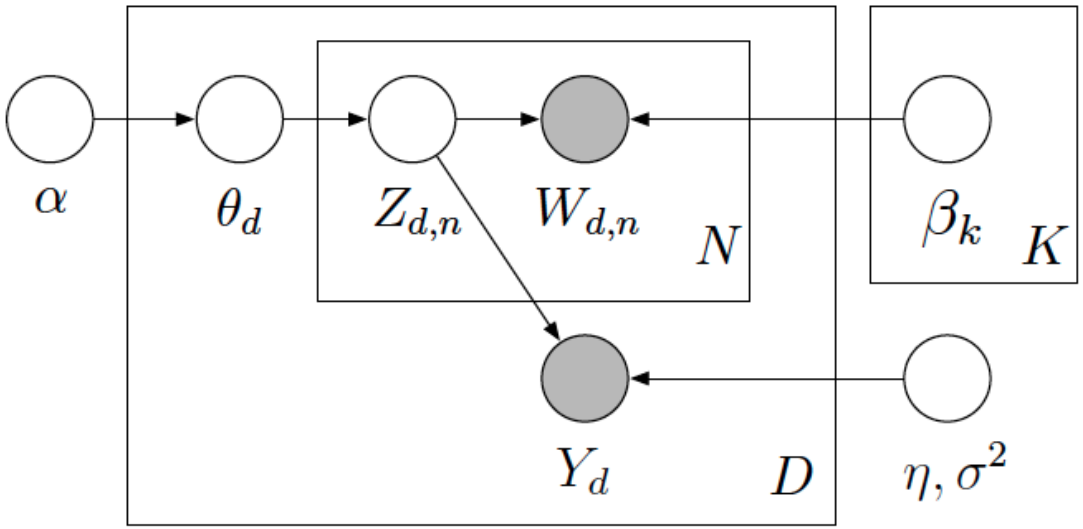
Supervised LDA



1. Draw topic proportions $\theta \mid \alpha \sim \text{Dir}(\alpha)$.
2. For each word
   - Draw topic assignment $z_n \mid \theta \sim \text{Mult}(\theta)$.
   - Draw word $w_n \mid z_n, \beta_{1:K} \sim \text{Mult}(\beta_{z_n})$.
3. Draw response variable $y \mid z_{1:N}, \eta, \sigma^2 \sim \text{N}(\eta^\top \bar{z}, \sigma^2)$, where

$$\bar{z} = (1/N) \sum_{n=1}^{N} z_n.$$

Supervised LDA



- The response variable y is drawn *after* the document because it depends on $z_{1:N}$, an assumption of **partial exchangeability**.
- Consequently, y is necessarily conditioned on the words.

Prediction

- Fit sLDA parameters to documents and responses. This gives:
  - topics $\beta_{1:K}$
  - coefficients $\eta_{1:K}$
- We have a new document $w_{1:N}$ with unknown response value.
- We predict y using the SLDA expected value:

$$\mathrm{E}\left[Y \mid w_{1:N}, \alpha, \beta_{1:K}, \eta, \sigma^2\right] = \eta^\top \mathrm{E}\left[\bar{Z} \mid w_{1:N}\right]$$
