

# Sketch of Solutions for Tutorial 3 and Homework 3

## Tutorial 3:

1. *Show that a graph with  $n$  vertices with vertex connectivity  $k$  has at least  $kn/2$  edges.* (3)

Vertex-connectivity  $k$  means that  $\delta(G) \geq k$ . Hence total number of edges = (Sum of all degrees)/2  $\geq kn/2$ .

2. *Prove that every edge cut in a graph must contain one branch from every spanning tree of the graph.* (3)

Suppose not, i.e., an edge cut  $X$  does not contain any branch of some spanning tree. But then,  $G - X$  is still connected, as a spanning tree can be built in  $G$ . Hence  $X$  cannot be an edge cut. This is a contradiction.

3. *Prove that an Eulerian graph cannot have a minimal edge cut with an odd number of edges.* (4)

Consider any minimal edge cut  $X$ . Then,  $G - X$  has exactly two components (or  $X$  will not be minimal). Since  $G$  is Eulerian,  $G$  can be decomposed into cycle. If a cycle lies entirely in one component, no edge of the cycle belongs to  $X$ . However, if a cycle lies partly in one component and partly in the other, there must be an even number of edges from that cycle in  $X$  (as if we traverse the cycle in any order starting from one component, for every edge going to the other component (and hence belongs to  $X$ ), there must be an edge coming back (and hence must also belong to  $X$ ).

So  $X$  contains an even number of edges from each of the cycles that  $G$  can be decomposed into. Hence the result.

## Homework 2:

1. Prove that no graph has a cut vertex of degree 1. (5)

Consider a cut vertex  $v$  of  $G$ . Then  $G-v$  has more than one component. Let  $(G-v)$  have components  $C_1, C_2, \dots, C_k, k > 1$ . Consider any two vertices  $x \in C_i$  and  $y \in C_j, i \neq j$ . Since  $G$  is connected, there is a path between  $x$  and  $y$  in  $G$ . Since  $C_i$  and  $C_j$  are in different components of  $G-v$ , there is no path between  $x$  and  $y$  in  $G-v$ . Hence the path between  $x$  and  $y$  in  $G$  must contain  $v$  (or the path would have remained on removal of  $v$ ). Also,  $v$  is not an endpoint of this path (as  $x, y \neq v$ ). Hence  $v$  must have at least two neighbors (the two nodes it is connected to in the path). Hence.  $d(v) > 1$ .

2. Prove that  $\kappa(G) = \kappa'(G)$  when  $G$  is a simple graph with  $\Delta(G) \leq 3$ . (5)

The case  $\Delta(G) = 1$  is obvious. For  $\Delta(G) = 2$ , if  $\delta(G) = 1$ ,  $\kappa(G) = \kappa'(G) = 1$  (remove the edge or the node connecting the degree 1 vertex with its neighbor. If  $\delta(G) = 2$ , each component is a cycle (min and max degree = 2 means degree of all nodes = 2), and  $\kappa(G) = \kappa'(G) = 2$ .

For  $\Delta(G) = 3$ , see proof of Theorem 4.1.11 in West. If  $\delta(G) = 3$ , it is a 3-regular graph, and the theorem proves it. If  $\delta(G) = 2$ , the proof is similar.

3. Let  $v$  be a cut vertex of a simple connected graph  $G$ . Prove that  $(G'-v)$  is connected. (5)

Since  $v$  is a cut vertex of  $G$ , let  $(G-v)$  have components  $C_1, C_2, \dots, C_k, k > 1$ .

Consider any two vertices  $x \in C_i$  and  $y \in C_j, i \neq j$ . Then  $(x, y) \notin E(G)$ . Therefore  $(x, y) \in E(G')$ . Thus any two vertices in two different components of  $G-v$  are connected by a direct edge in  $G'-v$ .

Now consider any two vertices  $(x, y)$  in the same component  $C_i$ . If  $(x, y) \notin E(G)$  then  $(x, y) \in E(G')$ . If  $(x, y) \in E(G)$ , then  $(x, y) \notin E(G')$ . But then, consider any node  $z \in C_j, i \neq j$ . We have already shown that  $(x, z) \in E(G'-v)$  and  $(y, z) \in E(G'-v)$ . Hence there is a path between  $x$  and  $y$  in  $(G'-v)$ .

Thus, there is a path between any two vertices in  $(G'-v)$ . hence  $(G'-v)$  is connected.

4. *Prove that a simple graph  $G$  is 2-connected if and only if for every triple  $(x, y, z)$  of distinct vertices,  $G$  has an  $(x,z)$  path through  $y$ .* (5)

**Only if:** Since  $G$  is 2-connected,  $x$  and  $y$  must lie on some cycle  $C_1$  and  $y$  and  $z$  must lie on some cycle  $C_2$ , and  $C_1$  and  $C_2$  has at least  $y$  in common. Now just think of the different cases possible (Case 1:  $C_1$  and  $C_2$  has only  $y$  in common and Case 2:  $C_1$  and  $C_2$  has more than one vertex in common. The second case will have subcases).

**If:**  $G$  is connected as there is a path between any two vertices. Suppose there is a cut-vertex  $v$ . Consider any two vertices  $x$  and  $y$  in two different components in  $G - \{v\}$ . Then, there exists a path from  $x$  to  $v$  through  $y$ . But this path cannot go through  $v$ . So there exists a path from  $x$  to  $y$  not including  $v$ . So they must be in the same component. Hence  $v$  cannot be a cut vertex. So  $G$  is 2-connected.

5. *Let  $G$  be a connected graph with at least 3 vertices. Form  $G'$  from  $G$  by adding an edge  $(x,y)$  in  $G'$  (if it is not already there in  $G$ ) whenever  $d(x,y) = 2$  in  $G$ . Prove that  $G'$  is 2-connected.* (5)

Suppose not. Then there exists a cut vertex  $v$  in  $G'$ . Since  $v$  is a cut vertex,  $\exists x, y \in V$  such that  $x, y$  are neighbors of  $v$ ,  $(x, y)$  is not an edge in  $G'$ , and  $x, y$  belongs to different components of  $G - v$ . This means  $d(x, y) > 2$  in  $G$ . Since no edges of  $G$  are removed, this means that at least one or both of  $x$  or  $y$  is at distance 2 from  $v$  in  $G$  (or they will not be at distance 2 in  $G'$ ). Without any loss of generality, let that node be  $x$ . Then,  $\exists z \in V$  such that  $z$  is a neighbor of both  $x$  and  $v$ . But then,  $d(z, y) = 2$  (if  $(y, v) \in E$ , or  $d(z, p) = 2$  (if  $d(y, v) = 2$  in  $G$  and  $p$  is the intermediate node in that path). But then, there must be an edge from  $z$  to  $y$  (or  $p$ ) in  $G'$ . Note that this is an edge between two direct neighbors of  $v$  in two different components, and this will be true for any such neighbors. Hence  $v$  cannot be a cut vertex. This is a contradiction.
