Algorithm Analysis

What is an algorithm ?

- **A clearly specifiable set of instructions**
 - **to solve a problem**
- **Given a problem**
 - **decide that the algorithm is correct**
- **Determine how much resource the algorithm will require**
 - **Time**
 - **Space**

Analysis of Algorithms

- **How much resource is required ?**
- **Measures for efficiency**
 - **Execution time** → **time complexity**
 - **Memory space** → **space complexity**
- **Observation :**
 - **The larger amount of input data an algorithm has, the larger amount of resource it requires.**
 - **Complexities are functions of the amount of input data (input size).**

What do we use for a yardstick?

- **The same algorithm will run at different speeds and will require different amounts of space when run on different computers, different programming languages, different compilers.**
- **But algorithms usually consume resources in some fashion that depends on the size of the problem they solve : n .**

Sorting integers

```
void sort (int A[], int N)
{
    int i, j, x;
    for (i=1; i<N; i++)
    {
        x = A[i];
        for (j=i; j>0 && x<A[j-1]; j- -)
            A[j] = A[j-1];
        A[j] = x;
    }
}
```

- We run this sorting algorithm on two different computers, and note the time (in ms) for different sizes of input.

Array size n	Computer 1	Computer 2
125	12.5	2.8
250	49.3	11.0
500	195.8	43.4
1000	780.3	72.9
2000	3114.9	690.5

Contd.

- **Computer 1:**

$$f_1(n) = 0.0007772 n^2 + 0.00305 n + 0.001$$

- **Computer 2 :**

$$f_2(n) = 0.0001724 n^2 + 0.00040 n + 0.100$$

- **Both are quadratic function of n.**
- **The shape of the curve that expresses the running time as a function of the problem size stays the same.**

Complexity classes

- The running time for different algorithms fall into different *complexity classes*.
 - Each complexity class is characterized by a different family of curves.
 - All curves in a given complexity class share the same basic shape.
- The *O-notation* is used for talking about the complexity classes of algorithms.

Introducing the language of O-notation

- For the quadratic function

$$f(n) = an^2 + bn + c$$

we will say that $f(n)$ is $O(n^2)$.

- We focus on the **dominant term**, and ignore the lesser terms; then throw away the coefficient.

Mathematical background

- **$T(N) = O(f(N))$** if there are positive constants c and n_0 such that $T(N) \leq c f(N)$ when $N \geq n_0$.

Meaning : As N increases, $T(N)$ grows no faster than $f(N)$.

The function T is eventually bounded by some multiple of $f(N)$. $f(N)$ gives an upper bound in the behavior of $T(N)$.

- **$T(N) = \Omega(g(N))$** if there are positive constants c and n_0 such that $T(N) \geq c f(N)$ when $N \geq n_0$.

Meaning : As N increases, $T(N)$ grows no slower than $g(N)$; $T(N)$ grows at least as fast as $g(N)$.

Contd.

- $T(N) = \theta(h(N))$ if and only if $T(N) = O(h(N))$
and $T(N) = \Omega(h(N))$

Meaning : As N increases, $T(N)$ grows as fast as $h(N)$.

- $T(N) = o(p(N))$ if $T(N) = O(p(N))$ and
 $T(N) \neq \theta(p(N))$

Meaning : As N increases, $T(N)$ grows slower than $p(N)$. $\lim_{n \rightarrow \infty} T(N)/p(N) = 0$.

Examples

- $\log_e n = O(n)$
- $n^{10} = o(2^n)$
- $3n^2 + 5n + 1 = \theta(n^2)$

Concepts in Analysis

1. Worst Case
2. Average case (expected value)
3. Operator count

Why is the analysis of algorithms important ?

**Can advance on hardware overcome inefficiency
of your algorithm ?**

→ NO !

Model of computation

- **A normal computer, instructions executed sequentially.**
 - **addition, multiplication, comparison, assignment, etc.**
 - **all are assumed to take a single time unit.**

Running time of algorithms

Assume speed S is 10^7 instructions per second.

size n	10	20	30	50	100	1000	10000
n	.001 ms	.002 ms	.003 ms	.005 ms	.01 ms	.1 ms	1 ms
$n \log n$.003 ms	.008 ms	.015 ms	.03 ms	.07 ms	1 ms	13 ms
n^2	.01 ms	.04 ms	.09 ms	.25 ms	1 ms	100 ms	10 s
n^3	.1 ms	.8 ms	2.7 ms	12.5 ms	100 ms	100 s	28 h
2^n	.1 ms	.1 s	100 s	3 y	3×10^{13} c	inf	inf

Maximum size solvable within 1 hour

speed complexity	S	100 S	1000 S
n	N1 = 3.6×10^{10}	100 N1	1000 N1
n log n	N2 = 1.2×10^9	85 N2	750 N2
n^2	N3 = 2×10^5	10 N3	30 N3
2^n	N4 = 35	N4+7	N4+10

Observations

- **There is a big difference between polynomial time complexity and exponential time complexity.**
- **Hardware advances affect only efficient algorithms and do not help inefficient algorithms.**

Maximum subsequence sum problem

- Given (possibly negative) integers $\langle A_1 A_2 \dots A_N \rangle$ find the maximum value of $\sum_{k=i}^j A_k$.
 - For convenience, the maximum subsequence sum is considered to be 0 if all the integers are negative.
- Example :
 - For input $\langle -2, 11, -4, 13, -5, 2 \rangle$ the answer is 20 (A_2 to A_4)

Algorithm 1

```
int MaxSubSum (int A[], int N) {  
    int thissum, maxsum, i,j,k;  
    1. maxsum = 0;  
    2. for (i=0; i<N; i++)  
    3.   for (j=i; j<N; j++)      {  
    4.     thissum = 0;  
    5.     for (k=i; k <= j; k++)  
    6.       thissum += A[k];  
    7.     if (thissum > maxsum)  
    8.       maxsum = thissum;  
    }  
    9. return maxsum;  
}
```

- The loop at line 2 is of size N.
- The second loop has size N-i.
- The third loop has size j-i+1
- Total : about N³ steps

$$\sum_{k=i}^j 1 = j-i+1$$

$$\sum_{j=i}^{N-1} (j-i+1) = (N-i+1)(N-i)/2$$

$$\sum_{i=0}^{N-1} (N-i+1)(N-i)/2 = (N^3 + 3N^2 + 2N)/6$$

Improve the running time

- Remove the second for loop
- Observe :
 - $\sum_{k=i}^j A_k = A_j + \sum_{k=i}^{j-1} A_k$

Algorithm 2

```
int MaxSubSum2 (int A[], int N)
{
    int thissum, maxsum, i, j;
1. maxsum = 0;
2. for (i=0; i<N; i++)
3. {
3. thissum = 0;
4.     for (j=i; j < N; j++)
5.     {
5.     thissum += A[j];
6.     if (thissum > maxsum)
7.     maxsum = thissum;
    }
    }
8. return maxsum;
}
```

Complexity :
 $O(N^2)$

Recursive algorithm

- **Divide & Conquer :**
 - **Divide:** Split the problem into two roughly equal subproblems, and solve recursively.
 - **Conquer:** Patch together the 2 solutions of the subproblems, and some additional work to get a solution for the whole problem.

Divide & Conquer

- **The maximum subsequence sum can be in one of three places :**
 - **occurs entirely in the left half of the input**
 - **occurs entirely in the right half**
 - **crosses the middle and is in both halves.**
- **1 & 2 can be solved recursively**
- **3 can be solved by finding the largest sum in the first half that includes the last element of the first half, and the largest element in the 2nd half that includes the 1st element in the 2nd half, and adding the two.**

First half	Second half
4 -3 5 -2	-1 2 6 -2

Algorithm 3

```
int maxsum (int A[], int left, int right) {
    int maxlsum, maxrtsum, maxlbsubsum, maxrbsum, lbsubsum, rbsubsum;
    int i, centre;
1.  if (left == right)
2.      if (A[left]>0) return A[left];
3.      else return 0;
4.  centre = (left + right)/2;
5.  maxlsum = maxsubsum(A,left,center);
6.  maxrtsum = maxsubsum(A, center+1, right);
7.  maxlbsubsum = lbsubsum = 0;
8.  for (i=centre; i>=left; i--)    {
9.      lbsubsum += A[i];
10. if (lbsubsum > maxlbsubsum)    maxlbsubsum = lbsubsum;
    }
```

Algorithm 3 : continued

```
11 maxrbsum = rbsum = 0;
12 for (i=centre+1; i<=right; i++) {
13     rbsum += A[i];
14     if (rbsum > maxrbsum) maxrbsum = rbsum;
15 }
15 return max(maxlsum, maxrtsum, maxlsum + maxrbsum);
}

int maxsubsum3 (int A[], int N) {
    return maxsum (A, 0, N-1);
}
```

Complexity

- $T(1) = 1$
 - $T(N) = 2 T(N/2) + O(N)$
 $= 2 T(N/2) + cN$
- $T(2) = 4$
 $T(4) = 12$
 $T(2^k) = N*(k+1) = N \log N + N$
 $= O(N \log N)$

Algorithm 4

```
int MaxSubSum4 (int A[], int N)
{
    int thissum, maxsum, j;
1. thissum = maxsum = 0;
2. for (j=0; j<N; j++)    {
3.     thissum += A[j];
4.     if (thissum > maxsum)
5.         maxsum = thissum;
6.     else if (thissum < 0)
7.         thissum = 0;
    }
8. return maxsum;
}
```

Complexity :
 $O(N)$

Thank You!
