

INTRODUCTION

CS10003: PROGRAMMING AND DATA STRUCTURES

What is this course?

PDS: Programming and Data structure

- Basically we will learn how to write programs
- Programs? Set of instructions written for a **computer**. Tell it what to do

What is this course?

What is this course?

PDS: Programming and Data structure

- Basically we will learn how to write programs
- Programs? Set of instructions written for a **computer**. Tell it what to do

General announcements about the course

- This is the PDS theory course. There is a Lab course that will run in parallel.
 - Theory course website: <https://cse.iitkgp.ac.in/pds/current>
 - Slides, announcements will be put up on the course website (you should check it frequently!)

Books:

1. Programming with C, Byron Gottfried
 2. The C Programming Language, Brian W Kernighan, Dennis M Ritchie
 3. Programming in ANSI C, E. Balaguruswamy
 4. Data Structures, S. Lipschutz, Schaum's Outline Series
- ... and many more options

More materials available at <http://cse.iitkgp.ac.in/pds/notes>

Evaluation Plan (Tentative)

- 2 Class tests (1 hour and 20 marks each)
 - CT 1: 5-Sep-2023 (Tuesday), 6:00pm (tentatively)
 - CT 2: 7-Nov-2023 (Tuesday), 6:00pm (tentatively)
 - **Weightage: 20% of the total marks**
- Mid-semester exam (2 hours and 60 marks)
 - Date/Time: Sept 2023 (TBD)
 - **Weightage: 30% of the total marks**
- End-semester exam (3 hours and 100 marks)
 - Date/Time: Nov 2023 (TBD)
 - **Weightage: 50% of the total marks**

Super powers of computer

- This machine can do **some tasks** blazingly fast, tirelessly
 - Thousands of complex mathematical operations in a second
- But...
 - You need to speak its language
 - Tell computers exactly what operations to do, step by step
 - Programming...

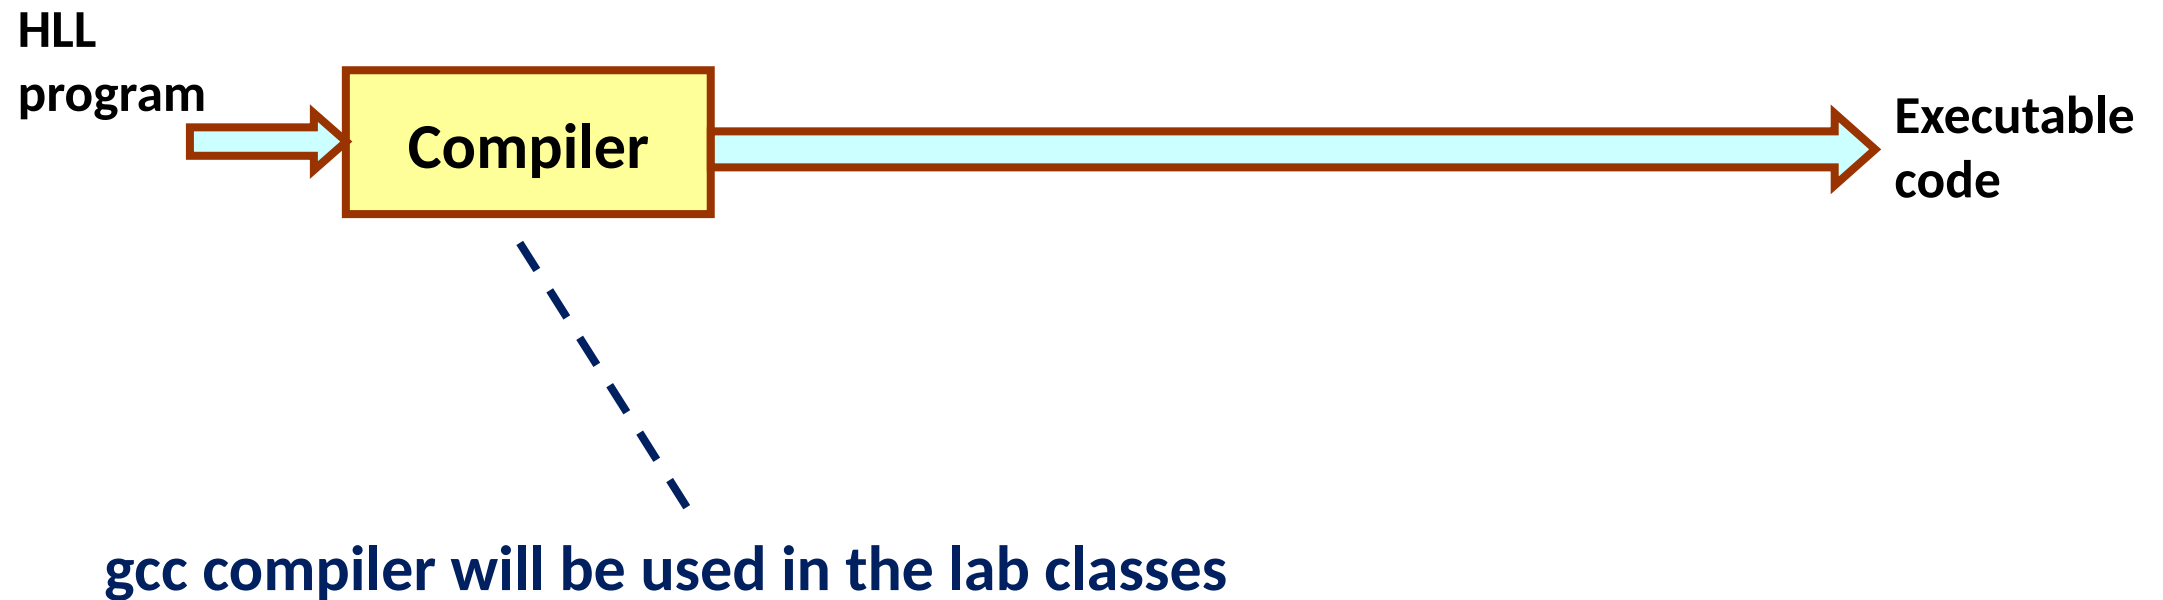

Three steps in writing programs

Step 1: Write the program in a high-level language (HLL - in your case, C)

Step 2: Compile the program using a C compiler

Step 3: Run / execute the program (ask the computer to execute it)

But, you can use instructions written by others: Libraries

Libraries: Pre-written instructions for complicated tasks

You can include these library names in your program and use their functionalities

Don't need to write those instructions yourself

gcc compiler will be used in the lab classes

This executable code is in binary
Computer understands only numbers, in binary (0 and 1)

Binary Representation

The decimal number system we use is base 10

- 10 digits, from 0 to 9, Positional weights $10^0, 10^1, 10^2, \dots$ from right to left for integers
- Example: $723 = 3 \times 10^0 + 2 \times 10^1 + 7 \times 10^2$

Numbers are represented inside computers in the base-2 system (Binary Numbers)

- Only two symbols/digits 0 and 1
- Positional weights of digits: $2^0, 2^1, 2^2, \dots$ from right to left for integers
- Example: $1101 \text{ in binary} = (1 \times 2^0) + (0 \times 2^1) + (1 \times 2^2) + (1 \times 2^3) = 13 \text{ in decimal}$

Bits and Bytes

- Bit – a single 1 or 0
- Byte – 8 consecutive bits
 - 2 bytes = 16 bits
 - 4 bytes = 32 bits
- Maximum integer that can be represented
 - in 1 byte = 255 (=11111111)
 - In 4 bytes = 4294967295 (= 32 1's)
- Number of integers that can be represented in 1 byte = 256 (the integers 0, 1, 2, 3,....255)

Problem Solving (the thought process)

Problem solving: typical flow

Step 1:

- Clearly specify the problem to be solved.

Step 2:

- Draw flowchart or write algorithm (represent the sequence of operations needed).

Step 3:

- Convert flowchart (algorithm) into program code.

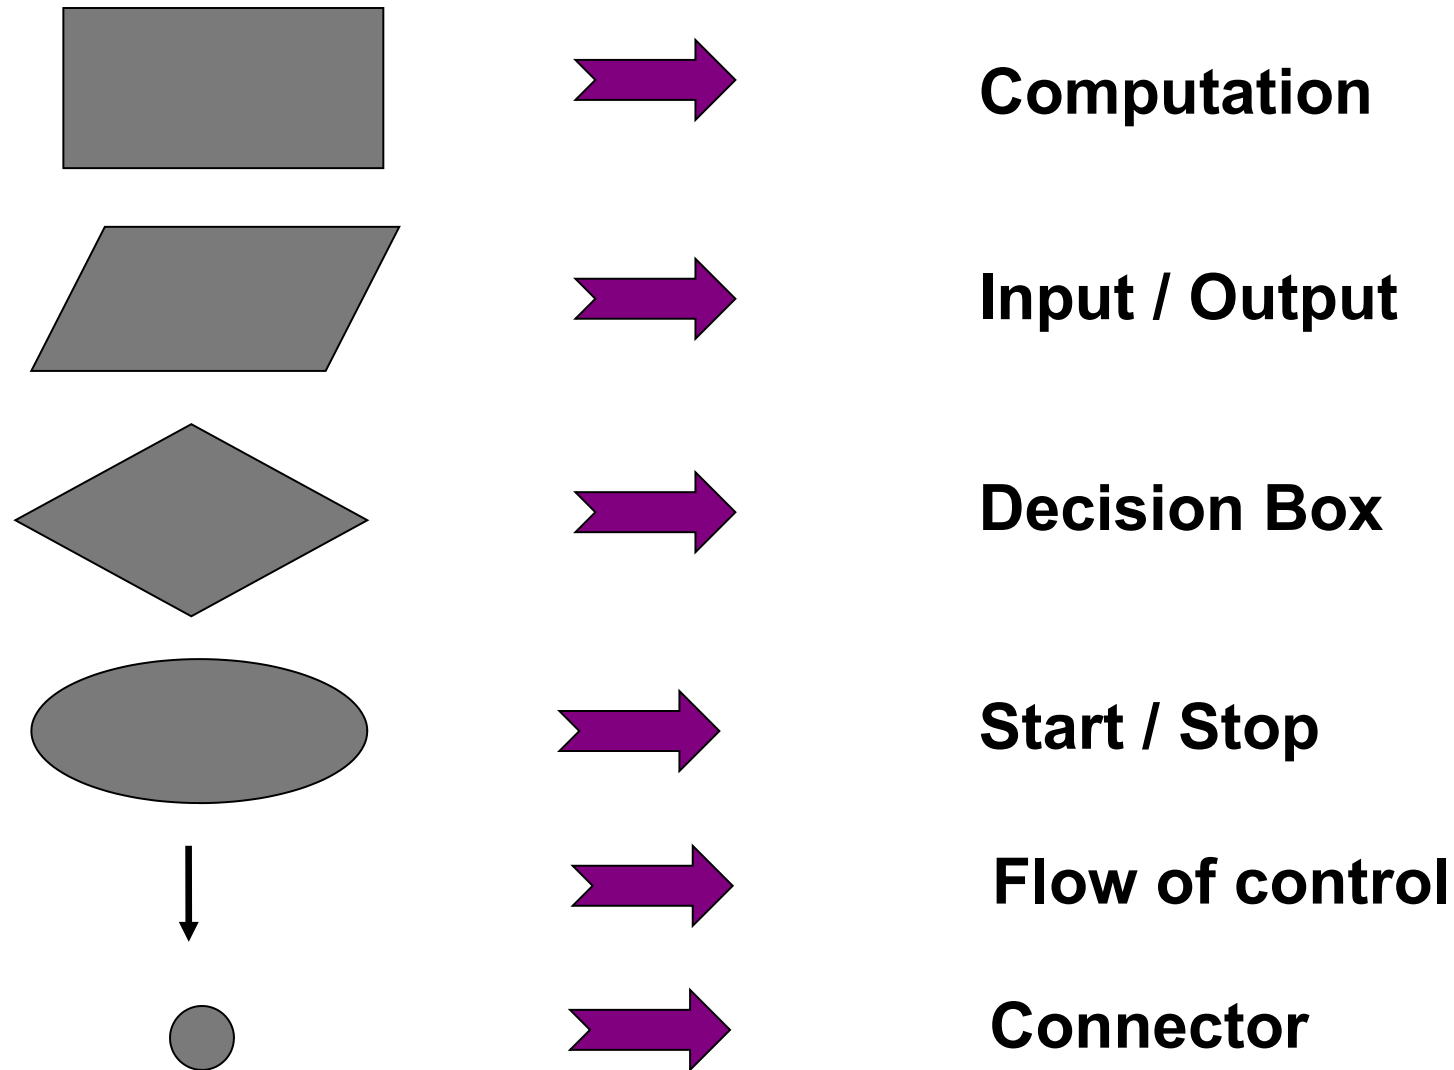

Step 4:

- Compile the program to get executable code.

Step 5:

- Execute the program on a computer.

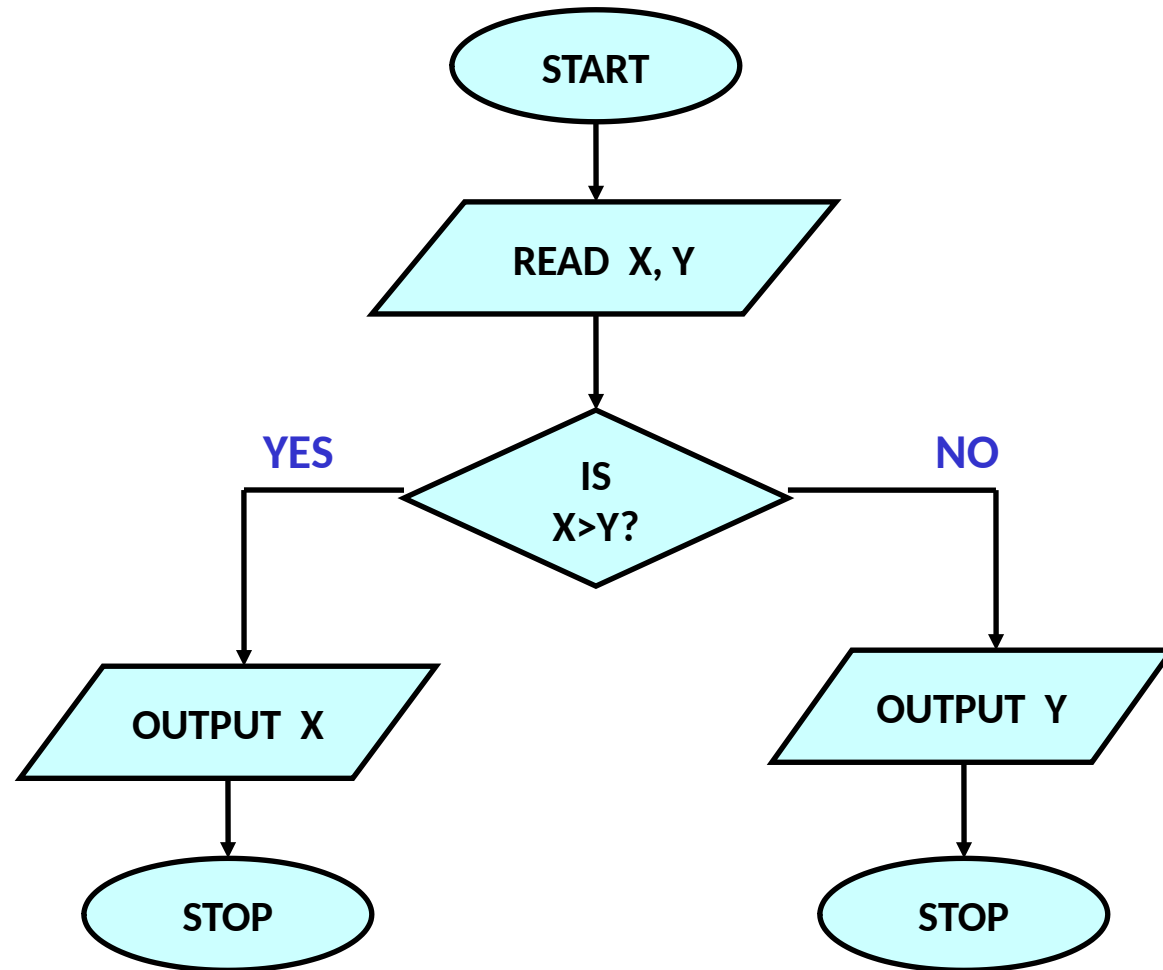

Flowchart: represent the sequence of operations as a diagram

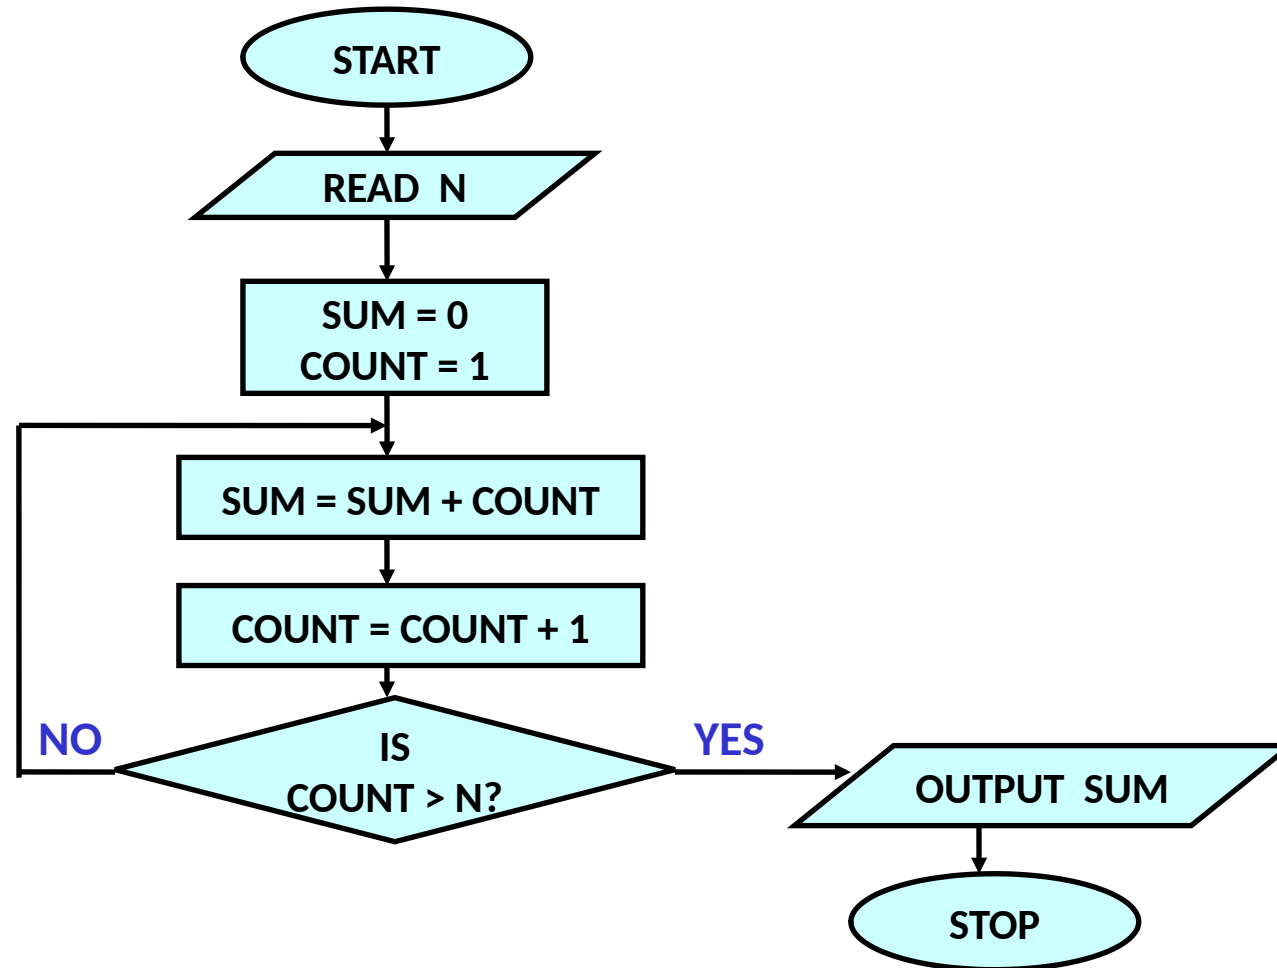

Flowchart: Example 1: adding three numbers

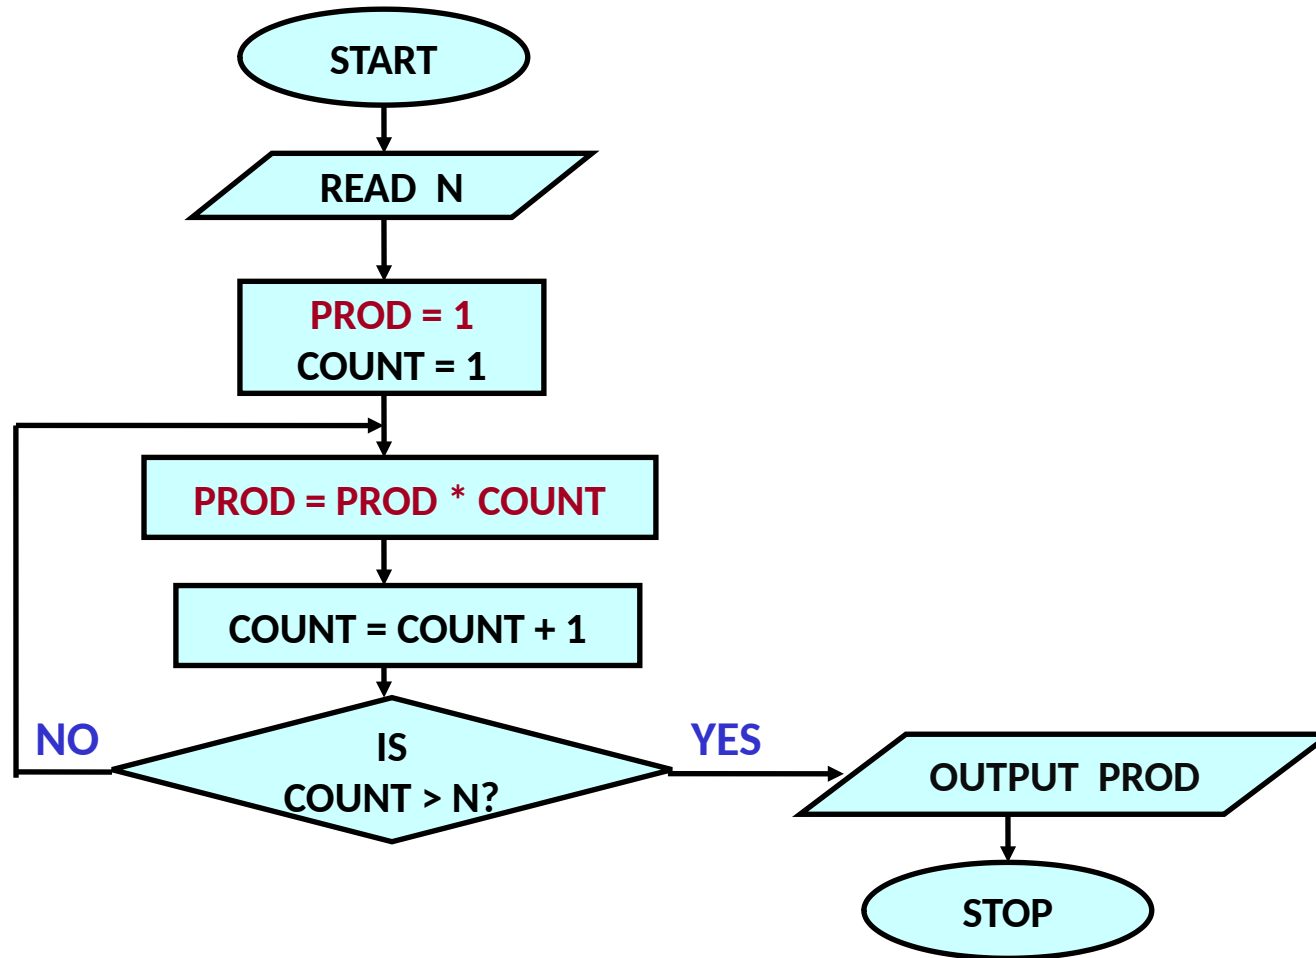

Flowchart: Example 2: find larger of two numbers

Flowchart: Example 3: sum first N integers

Flowchart: Example 4: compute factorial of a number

Fundamentals of C

First C program – print on screen

```
#include <stdio.h>

int main()
{
    printf ("Hello, World! \n") ;
    return 0;
}
```

Output

Hello, World!

A Simple C program

```
#include <stdio.h>

int main()
{
    int x, y, sum, max;
    scanf("%d%d", &x, &y);
    sum = x + y;
    if (x > y) max = x;
    else max = y;
    printf ("Sum = %d\n", sum);
    printf ("Larger = %d\n", max);
    return 0;
}
```

When you run the program

Output after you type 15 and 20

```
15 20
Sum = 35
Larger = 20
```

Structure of a C program

- A collection of **functions** (we will see what they are later)
- Exactly one special function named **main()** must be present. Program always starts from there.
- Each function has different types of statements
 - **variable declarations, assignment, condition check, looping etc.**
- Statements are executed one by one in top-down order (though some special instructions differ from this top-down order)

Things you will see in a C program (we will look at all these one by one)

- Variables
- Constants
- Expressions (Arithmetic, Logical, Assignment)
- Statements (Declaration, Assignment, Control (Conditional/Branching, Looping))
- Arrays
- Functions
- Structures
- Pointers

The C Character Set

The C language alphabet

- Uppercase letters 'A' to 'Z'
- Lowercase letters 'a' to 'z'
- Digits '0' to '9'
- Certain special characters:

!	#	%	^	&	*	()
-	_	+	=	~	[]	\
	;	:	'	"	{	}	,
.	<	>	/	?			

A C program whitespace characters (space, tab, ...)

Variables

- Very important concept for programming
- Can store any temporary result while executing a program
- **Can have only one value assigned to it at any given time**
- The value of a variable can be changed during the execution of the program

- Variables are stored in the computer's memory
- Memory is a list of consecutive storage locations, each having a unique address
- Four aspects of a variable:
 - The **value** stored in the variable
 - The **type** of the variable – decides what type of value can be stored (integer, real, etc.)
 - The variable **name** is used to refer to the value of the variable
 - A variable is stored at a particular location of the memory, called its **address**

MEMORY

Example

```
#include <stdio.h>
int main( )
{
    int x;
    int y;

    x=1;
    y=3;

    printf("x = %d, y= %d\n", x, y);

    return 0;
}
```

The = sign in a C program does NOT denote equality

We are actually **assigning a value to a variable**, i.e., storing a particular value into the variable

Variables in Memory

Instruction sequence

int X

X = 10

X = 20

X = X + 1

X = X * 5

Memory

X

?

(may contain whatever value at the beginning)

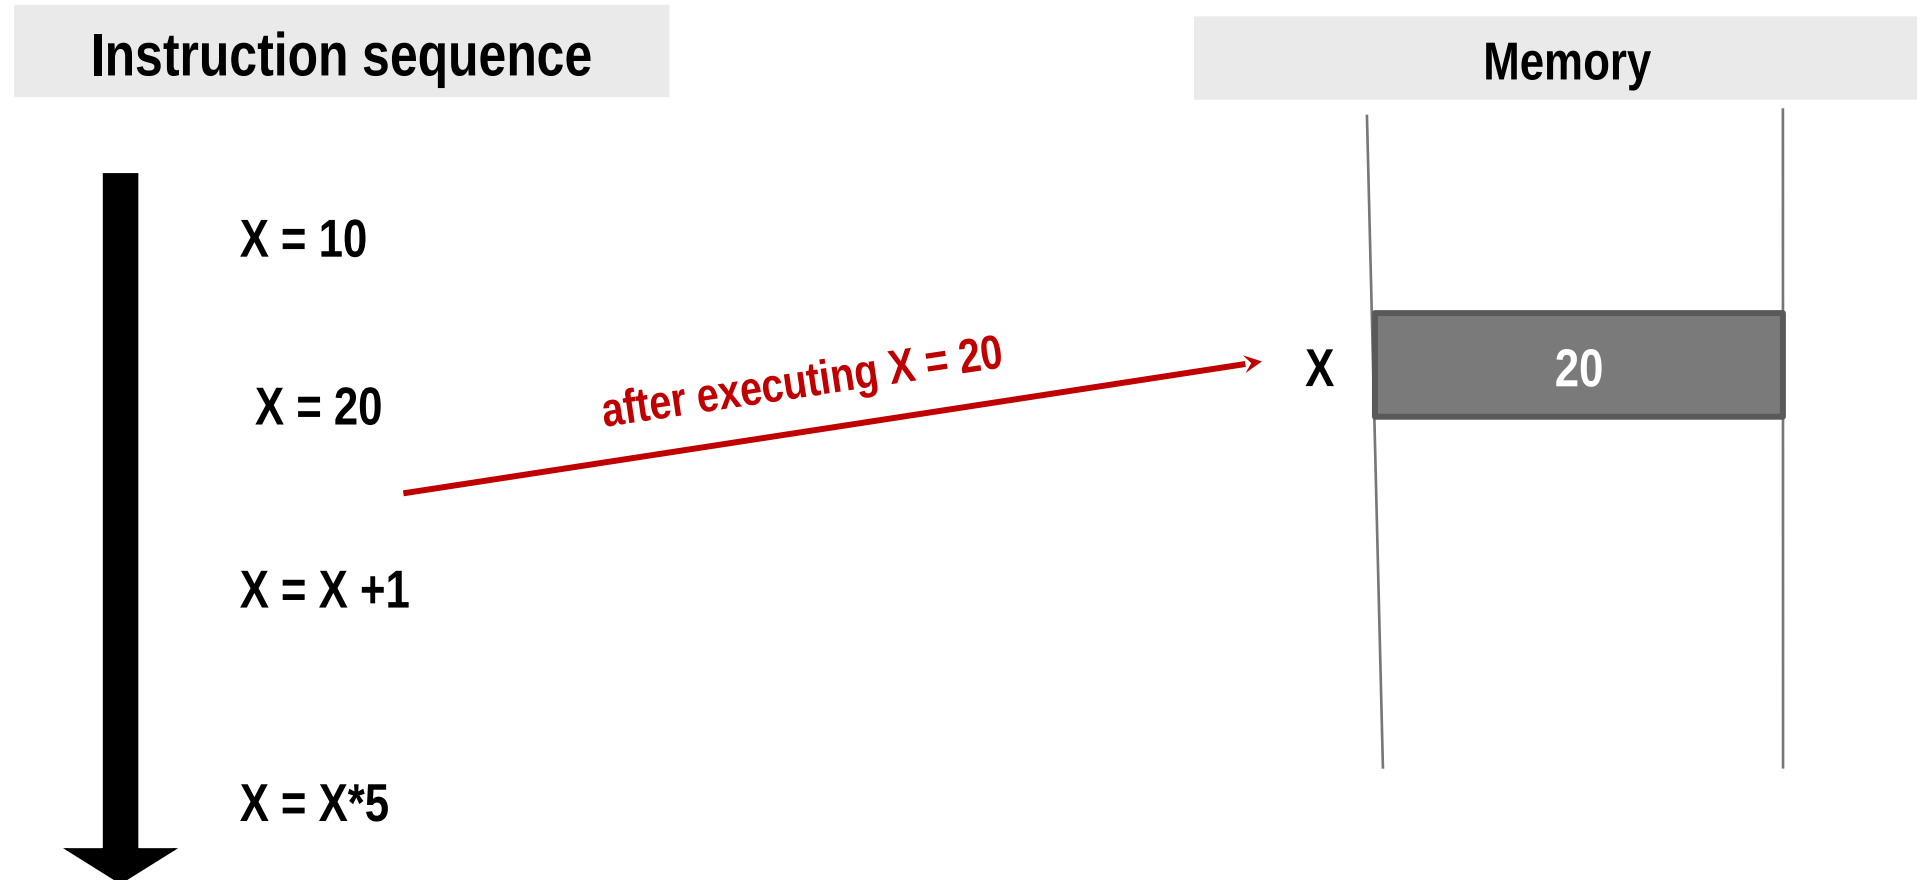

A variable can have only one value assigned to it at any given time during the execution of the program

Variables in Memory

A variable can have only one value assigned to it at any given time during the execution of the program

Variables in Memory

A variable can have only one value assigned to it at any given time during the execution of the program

Variables in Memory

A variable can have only one value assigned to it at any given time during the execution of the program

Variables in Memory

A variable can have only one value assigned to it at any given time during the execution of the program

Variables in Memory

Instruction sequence

$X = 20$

$Y = 15$

$X = Y + 3$

$Y = X / 6$

Memory

X

?

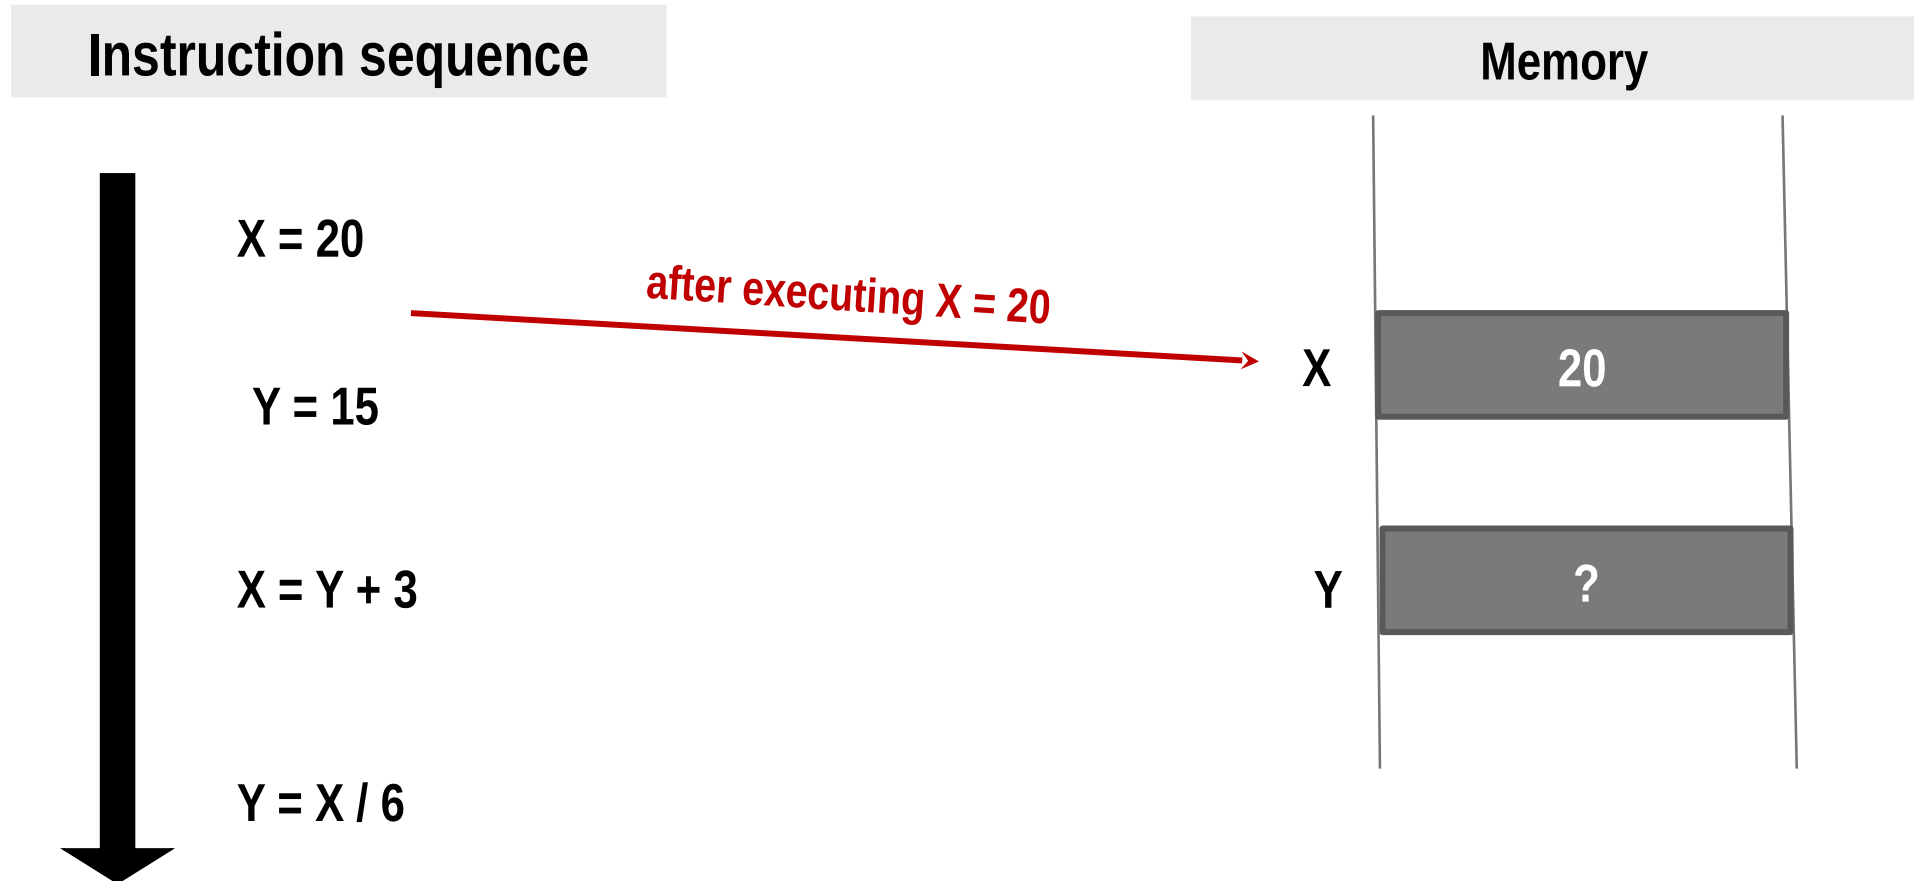

(may contain whatever value at the beginning)

Y

?

(may contain whatever value at the beginning)

Variables in Memory

Variables in Memory

Instruction sequence

$X = 20$

$Y = 15$

$X = Y + 3$

$Y = X / 6$

Memory

X

20

Y

15

after executing $Y = 15$

Variables in Memory

Note: Y does not change, only X changes after execution of this instruction

Variables in Memory

Data Types

- Each variable has a **type**, indicates what type of values the variable can hold
- Four common data types in C (there are others)
 - **int** - can store integers (usually 4 bytes)
 - **float** - can store single-precision floating point numbers (usually 4 bytes)
 - **double** - can store double-precision floating point numbers (usually 8 bytes)
 - **char** - can store a character (1 byte)

Normalized numbers in Single Precision Format

The normalized numbers are

$$(-1)^s 1.f \times 2^{E-127}$$

Here, **s** is the sign bit, **f** is the mantissa (fractional part), and **E** is the exponent (plus 127). The 1 before the binary point is not stored.

IEEE standards for floating-point representation

a. Single Precision

b. Double Precision

Example

Show the representation of the normalized number $+ 1.01000111001 \times 2^6$.

Solution

The sign is **positive**. The Excess_127 representation of the exponent is **133**.
You add extra 0s on the right to make it 23 bits. The number in memory is stored as:

0 **10000101** **01000111001****00000000000000000000000**

Rules and good practices

- First rule of variable use: **Must declare a variable** (specify its **type** and **name**) before using it anywhere in your program
- All variable declarations should ideally be at the beginning of the main() or other functions
 - There are exceptions, we will see later
- A value can also be assigned to a variable at the time the variable is declared.

```
int  speed = 30;  
char flag = 'y';
```

Initialization of a variable

Variable Names

- Sequence of letters and digits
- First character must be a letter or '_'
- No special characters other than '_'
- No blank in between
- Names are **case-sensitive** (**max** and **Max** are two different names)

- Examples of valid names:

i rank1 MAX max Min class_rank _Average

- Examples of invalid names:

a's fact rec 2sqroot class,rank

More Valid and Invalid Names (Identifiers)

Valid identifiers

X

abc

simple_interest

a123

LIST

stud_name

Empl_1

Empl_2

_avg_empl_salary

Invalid identifiers

10abc

my-name

“hello”

simple interest

(area)

%rate

C Keywords

- Specific terms used by the C language having specific meaning, **cannot** be used as variable names
- Examples:
`int, float, char, double, main, if else, for, while, do, struct, union, typedef, enum, void, return, signed, unsigned, case, break, sizeof,....`
- There are others, see textbook...

Example 1

```
#include <stdio.h>
```

```
int main()
```

```
{
```

```
    int x, y, sum;
```

Three integer type variables declared

```
    scanf ("%d%d", &x, &y);
```

```
    sum = x + y;
```

Values assigned

```
    printf( "%d plus %d is %d\n",  
            x, y, sum );
```

```
    return 0;
```

```
}
```

15 23

15 plus 23 is 38

Example 2

```
#include <stdio.h>
int main()
{
    float x, y;      /* Two floating point variables declared */
    int d1, d2 = 10; /* Integer variable d2 is initialized to 10 */

    scanf("%f%f%d",&x, &y, &d1);
    printf( "%f plus %f is %f\n", x, y, x + y);
    printf( "%d minus %d is %d\n", d1, d2, d1 - d2);
    return 0;
}
```

Input: scanf function

- Performs input from keyboard
- It requires a **format string** and a **list of variables** into which the value received from the keyboard will be stored
- format string = individual groups of characters (usually '%' sign, followed by a conversion character), with one character group for each variable in the list

```
int a, b;
```

```
float c;
```

```
scanf( "%d%d%f", &a, &b, &c );
```

Format string

Variable list (note the & before each variable name)

Commonly used conversion characters

c for char type variable

d for int type variable

f for float type variable

lf for double type variable

Examples

```
scanf ("%d", &size) ;
```

- Reads one integer from keyboard into an **int** type variable named **size**

```
scanf ("%c", &nextchar) ;
```

- Reads one character from keyboard into a **char** type variable named **nextchar**

```
scanf ("%f", &length) ;
```

- Reads one floating point (real) number from keyboard into a **float** type variable named **length**

```
scanf ("%d%d", &a, &b);
```

- Reads two integers from keyboard, the first one in an **int** type variable named **a** and the second one in an **int** type variable named **b**

Important

- `scanf()` will wait for you to type the input from the keyboard
- You must type the same number of inputs as the number of %'s in the format string
- **Example:** if you have `scanf ("%d%d",...)`, then you must type two integers (in same line or different lines), otherwise `scanf()` will just wait and the next statement will not be executed

Reading a single character

- A single character can be read using `scanf` with `%c`
- It can also be read using the `getchar()` function

```
char c;
```

```
...
```

```
c = getchar();
```

- Program waits at the `getchar()` line until a character is typed, and then reads it and stores it in `c`

Output: **printf** function

- Performs output to the standard output device (typically defined to be the screen)
- It requires a **format string** in which we can specify:
 - The text to be printed out
 - Specifications on how to print the values

```
printf ("The number is %d\n", num);
```

 - The format specification %d causes the value listed after the format string to be embedded in the output as a decimal number in place of %d
 - Output will appear as: **The number is 125**

General syntax of printf()

`printf (format string, arg1, arg2, ..., argn);`

- format string refers to a string containing formatting information and data types of the arguments to be output
- the arguments arg1, arg2, ... represent list of variables/expressions whose values are to be printed
- The conversion characters are the same as in scanf
- Examples:
 - `printf ("Average of %d and %d is %f", a, b, avg);`
 - `printf ("Hello \nGood \nMorning \n");`
 - `printf ("%3d %3d %5d", a, b, a*b+2);`
 - `printf ("%7.2f %5.1f", x, y);`
- Many more options are available for both printf and scanf – read from the book

More Examples

(Explain the outputs to test if you understood format strings etc.)

More point

```
#include <stdio.h>

int main()
{
    printf ("Hello, World! ") ;
    printf ("Hello \n World! \n") ;
    return 0;
}
```

Output

```
Hello, World! Hello
World!
```

Some more point

```
#include <stdio.h>

int main()
{
    printf ("Hello, World! \n") ;
    printf ("Hello \n World! \n") ;
    printf ("Hell\no \t World! \n") ;
    return 0;
}
```

Output

```
Hello, World!
Hello
World!
Hell
o      World!
```

Some more point

```
#include <stdio.h>

int main()
{
    float f1, f2;
    int x1, x2;

    printf("Enter values for f1 and f2: \n");
    scanf("%f%f", &f1, &f2);

    printf("Enter values for x1 and x2: \n");
    scanf("%d%d", &x1, &x2);

    printf("f1 = %f, f2 = %5.2f\n", f1, f2);
    printf("x1 = %d, x2 = %10d\n", x1, x2);

    return 0;
}
```

Output

```
Enter values for f1 and f2:
23.5  14.326
Enter values for x1 and x2:
54    7
f1 = 23.500000, f2 = 14.33
x1 = 54, x2 =          7
```

Can you explain why 14.326
got printed as 14.33?

Practice Problems

Write C programs to

1. Read two integers and two floating point numbers, each in a separate `scanf()` statement (so 4 `scanf`'s) and print them with separate `printf` statements (4 `printf`'s) with some nice message
2. Repeat 1, but now read all of them in a single `scanf` statement and print them in a single `printf` statement
3. Repeat 1 and 2 with other data types like `double` and `char`
4. Repeat 1 and 2, but now print all real numbers with only 3 digits after the decimal point
5. Read 4 integers in a single `scanf` statement, and print them (using a single `printf` statement) in separate lines such that the last digit of each integer is exactly 10 spaces away from the beginning of the line it is printed in (the 9 spaces before will be occupied by blanks or other digits of the integer). Remember that different integers can have different number of digits
6. Repeat 5, but now the first integer of each integer should be exactly 8 spaces away from the beginning of the line it is printed in.
