Let  $a_1, a_2, \dots, a_n$  be a permutation of the set  $\{1, 2, \dots, n\}$ . Defined below are some notions about permutations.

- An *inversion* of the permutation is a pair  $(a_i, a_j)$  such that  $i < j$  and  $a_i > a_j$ .
- The *inversion table*  $b_1, b_2, \dots, b_n$  of the permutation is defined by setting  $b_j$  as the number of inversions whose second component is  $j$ .
- The *index* of the permutation is the sum of all subscripts  $j$  such that  $a_j > a_{j+1}$ .

For example, the permutation 2, 5, 4, 1, 3 has 6 inversions: (2, 1), (5, 4), (5, 1), (5, 3), (4, 1) and (4, 3). The inversion table is given by 3, 0, 2, 1, 0. And the index is  $2 + 3 = 5$ .

Given a positive integer  $n$ , your task is to print all permutations of  $1, 2, \dots, n$  along with the number of inversions and the index for each permutation. Described below is an algorithm for the same.

- Write a function *init* to store  $1, 2, \dots, n$  in an array  $A[1, \dots, n]$ . Define a direction (+1, -1 or 0) for each element of  $A$  and store them in a separate array  $D[1, \dots, n]$ . Initialise  $D$  as follows:  $D[1] = 0$  and  $D[i] = -1$  for all  $2 \leq i \leq n$ . Note that +1, -1 indicate right and left respectively. Define a variable *invCount* that stores the number of inversions for the current permutation stored in  $A$ , initialised to 0. Use dynamic memory allocation to create  $A$  and  $D$ .
- Write a function *index* that computes and returns the index for the permutation stored in  $A$ . The index can be computed by making one pass over  $A$ .
- Define a function *genNext* that updates  $A$  to contain the next permutation as follows: find the largest number with non-zero direction (say,  $k = A[j]$ ); swap  $k$  with its neighbour in the indicated direction (i.e.,  $D[j]$ ). If after the swap, the larger of the two numbers swapped precedes the other in  $A$ , then increment *invCount*; otherwise decrement it.

Update  $D$  as follows: if the chosen element ( $k$ ) has reached position 1 or  $n$ , or if the next element in the same direction is greater than  $k$ , then set the direction of  $k$  as 0. Also, modify the direction of all the elements greater than  $k$  with 0 direction so that they point towards  $k$ .

Return *invCount*.

- In the *main()* function, read  $n$  from the user, call *init* and then repeatedly do the following until all numbers in  $A$  have direction 0: call *genNext*; call *index*; print the permutation stored in  $A$ , followed by the number of inversions (returned by *genNext*) and its index in one line (appropriately spaced). (You should create pointers for  $A$  and  $D$  in *main()* and pass them to the functions appropriately.)

### Sample Output 1

n = 3

Permutation	Inversions	Index
1 2 3	0	0
1 3 2	1	2
3 1 2	2	1
3 2 1	3	3
2 3 1	2	2
2 1 3	1	1
