Graph Coloring

K-coloring

- A k-coloring of G is a labeling $f:V(G) \rightarrow \{1, ..., k\}$.
 - The labels are colors
 - The vertices with color *i* are a color class
 - A k-coloring is proper if $x \leftrightarrow y$ implies $f(x) \neq f(y)$
 - A graph G is *k*-colorable if it has a proper *k*-coloring
 - The chromatic number $\chi(G)$ is the maximum k such that G is k-colorable
 - If $\chi(G) = k$, then G is *k*-chromatic
 - If $\chi(G) = k$, but $\chi(H) < k$ for every proper subgraph H of G, then G is color-critical or k-critical

Order of the largest clique

 Let α(G) denote the *independence number* of G, and ω(G) denote the order of the largest complete subgraph of G.

– χ (G) may exceed ω (G). Consider G = C_{2r+1} \vee K_s

Cartesian Product

- The Cartesian product of graphs G and H, written as G□H, is the graph with vertex set V(G) X V(H) specified by putting (*u*,*v*) adjacent to (*u'*,*v'*) if and only if
 - (1) u = u' and $vv' \in E(H)$, or
 - (2) v = v' and uu' $\in E(G)$

A graph G is *m*-colorable if and only if G□K_m has an idependent set of size n(G).
 Also: χ(G□H) = max{ χ(G), χ(H) }

Algorithm Greedy-Coloring

The greedy coloring with respect to a vertex ordering v₁,..., v_n of V(G) is obtained by coloring vertices in the order v₁,..., v_n, assigning to v_i the smallest indexed color not already used on its lower-indexed neighbors.

Results

- $\chi(G) \leq \Delta(G) + 1$
- If G is an interval graph, then $\chi(G) = \omega(G)$
- If a graph G has degree sequence d₁ ≥...≥ d_n, then χ(G) ≤ 1 + max_i min{ d_i, i−1}

More results

- If H is a k-critical graph, then $\delta(H) \ge k-1$
- If G is a graph, then $\chi(G) \leq 1 + \max_{H \subseteq G} \delta(H)$
- Brooks Theorem:

If G is a connected graph other than a clique or an odd cycle, then $\chi(G) \le \Delta(G)$.

Mycielski's Construction

 Mycielski found a construction that builds from any given k-chromatic triangle-free graph G a k+1-chromatic triangle-free supergraph G'.

- Given G with vertex set V = { $v_1,...,v_n$ }, add vertices U = { $u_1,...,u_n$ } and one more vertex w.

- Beginning with G'[V] = G, add edges to make u_i adjacent to all of $N_G(v_i)$, and then make N(w) = U. Note that U is an independent set in G'.

Critical Graphs

- Suppose that G is a graph with χ(G) > k and that X,Y is a partition of V(G). If G[X] and G[Y] are k-colorable, then the edge cut [X,Y] has at least k edges.
- [Dirac] Every *k*-critical graph is *k*-1 edge-connected.

Suppose S is a set of vertices in a graph G. An Scomponent of G is an induced subgraph of G whose vertex set consists of S and the vertices of a component of G - S.

 If G is k-critical, then G has no cutset of vertices inducing a clique. In particular, if G has a cutset S={x,y}, then x and y are not adjacent and G has an S-component H such that χ(H + xy) ≥ k.

Chromatic Recurrence

The function $\chi(G;k)$ counts the mappings $f: V(G) \rightarrow [k]$ that properly color G from the set $[k] = \{1,...,k\}$. In this definition, the *k*-colors need not all be used, and permuting the colors used produces a different coloring.

 If G is a simple graph and e ∈ E(G), then χ(G; k) = χ(G − e; k) − χ(G.e; k)

Line Graphs

The *line graph* of G, written L(G), is a simple graph whose vertices are the edges of G, with $ef \in E(L(G))$ when e and f share a vertex of G.

- An Eulerian circuit in G yields a spanning cycle in L(G). The converse need not hold
- A matching in G is an independent set in L(G); we have α'(G) = α(L(G))

Edge Coloring

A *k*-edge-coloring of G is a labeling $f: E(G) \rightarrow [k]$

- The labels are colors
- The set of edges with one color is a color class.
- A k-edge-coloring is proper if edges sharing a vertex have different colors; equivalently, each color class is a matching
- A graph is *k*-edge-colorable if it has a proper *k*edge-coloring
- The edge-chromatic-number χ'(G) of a loop-less graph G is the least k such that G is k-edgecolorable

Results

- $\chi'(G) \ge \Delta(G)$.
- If G is a loop-less graph, then $\chi'(G) \le 2\Delta(G) 1$.
- If G is bipartite, then $\chi'(G) = \Delta(G)$.

A regular graph G has a Δ (G)-edge coloring if and only if it decomposes into 1-factors. We say that G is *1-factorable*.

 Every simple graph with maximum degree ∆ has a proper ∆+1-edge-coloring.
