Module 07: Programming in C++

Reference & Pointer

Intructors: Abir Das and Sourangshu Bhattacharya

Department of Computer Science and Engineering
Indian Institute of Technology, Kharagpur

{*abir, sourangshu*}*@cse.iitkgp.ac.in*

Slides taken from NPTEL course on Programming in Modern C++

by **Prof. Partha Pratim Das**

Module Objectives

- Understand References in C++
- Compare and contrast References and Pointers

Module Outline

- Reference variable or Alias
  - Basic Notion
  - Call-by-reference in C++
- Example: Swapping two number in C
  - Using Call-by-value
  - Using Call-by-address
- Call-by-reference in C++ in contrast to Call-by-value in C
- Use of `const` in Alias / Reference
- Return-by-reference in C++ in contrast to Return-by-value in C
- Differences between References and Pointers

Reference

- A reference is an alias / synonym for an existing variable

```
int i = 15;   // i is a variable
int &j = i;   // j is a reference to i
```

i	← variable
15	← memory content
200	← address &i = &j
j	← alias or reference

Program 07.01: Behavior of Reference

```
#include <iostream>
using namespace std;

int main() {
    int a = 10, &b = a; // b is reference of a

    // a and b have the same memory location
    cout << "a = " << a << ", b = " << b << ". " << "&a = " << &a << ", &b = " << &b << endl;

    ++a; // Changing a appears as change in b
    cout << "a = " << a << ", b = " << b << endl;

    ++b; // Changing b also changes a
    cout << "a = " << a << ", b = " << b << endl;
}
```

```
a = 10, b = 10. &a = 002BF944, &b = 002BF944
a = 11, b = 11
a = 12, b = 12
```

- a and b have the *same memory location* and hence *the same value*
- Changing one changes the other and vice-versa

Pitfalls in Reference

Wrong declaration	Reason	Correct declaration
`int& i;`	no variable (address) to refer to – must be initialized	`int& i = j;`
`int& j = 5;`	no address to refer to as `5` is a *constant*	`const int& j = 5;`
`int& i = j + k;`	only temporary address (result of `j + k`) to refer to	`const int& i = j + k;`

```
#include <iostream>
using namespace std;

int main() {
    int i = 2;
    int& j = i;
    const int& k = 5;      // const tells compiler to allocate a memory with the value 5
    const int& l = j + k; // Similarly for j + k = 7 for l to refer to

    cout << i << ", " << &i << endl;    // Prints: 2, 0x61fef8
    cout << j << ", " << &j << endl;    // Prints: 2, 0x61fef8
    cout << k << ", " << &k << endl;    // Prints: 5, 0x61fefc
    cout << l << ", " << &l << endl;    // Prints: 7, 0x61ff00
}
```

C++ Program 07.02: Call-by-reference

```
#include <iostream>
using namespace std;

void Function_under_param_test( // Function prototype
    int&, // Reference parameter
    int); // Value parameter

int main() { int a = 20;
    cout << "a = " << a << ", &a = " << &a << endl << endl;
    Function_under_param_test(a, a); // Function call
}
void Function_under_param_test(int &b, int c) {  // Function definition
    cout << "b = " << b << ", &b = " << &b << endl << endl;
    cout << "c = " << c << ", &c = " << &c << endl << endl;
}
------- Output -------
a = 20, &a = 0023FA30
b = 20, &b = 0023FA30   // Address of b is same as a as b is a reference of a
c = 20, &c = 0023F95C   // Address different from a as c is a copy of a
```

- Param `b` is *call-by-reference* while param `c` is *call-by-value*
- Actual param `a` and formal param `b` get the *same value* in called function
- Actual param `a` and formal param `c` get the *same value* in called function
- Actual param `a` and formal param `b` get the *same address* in called function
- However, actual param `a` and formal param `c` have *different addresses* in called function

C Program 07.03: Swap in C

Call-by-value – wrong

```
#include <stdio.h>

void swap(int, int); // Call-by-value
int main() { int a = 10, b = 15;
    printf("a= %d & b= %d to swap\n", a, b);
    swap(a, b);
    printf("a= %d & b= %d on swap\n", a, b);
}
void swap(int c, int d) { int t;
    t = c; c = d; d = t;
}
```

- a= 10 & b= 15 to swap
- a= 10 & b= 15 on swap // No swap

- Passing values of a=10 & b=15
- In callee; c = 10 & d = 15
- Swapping the values of c & d
- No change for the values of a & b in caller
- Swapping the value of c & d instead of a & b

Call-by-address – right

```
#include <stdio.h>

void swap(int *, int *); // Call-by-address
int main() { int a=10, b=15;
    printf("a= %d & b= %d to swap\n", a, b);
    swap(&a, &b);  // Unnatural call
    printf("a= %d & b= %d on swap\n", a, b);
}
void swap(int *x, int *y) { int t;
    t = *x; *x = *y; *y = t;
}
```

- a= 10 & b= 15 to swap
- a= 15 & b= 10 on swap // Correct swap

- Passing Address of a & b
- In callee x = Addr(a) & y = Addr(b)
- Values at the addresses is swapped
- Desired changes for the values of a & b in caller
- It is correct, but C++ has a better way out

Program 07.04: Swap in C & C++

C Program: Call-by-value – wrong

```
#include <stdio.h>

void swap(int, int); // Call-by-value
int main() { int a = 10, b = 15;
    printf("a= %d & b= %d to swap\n",a,b);
    swap(a, b);
    printf("a= %d & b= %d on swap\n",a,b);
}
void swap(int c, int d) { int t ;
    t = c; c = d; d = t;
}
```

- a= 10 & b= 15 to swap
- a= 10 & b= 15 on swap // No swap

- Passing values of a=10 & b=15
- In callee; c = 10 & d = 15
- Swapping the values of c & d
- No change for the values of a & b in caller
- Here c & d do not share address with a & b

C++ Program: Call-by-reference – right

```
#include <iostream>
using namespace std;
void swap(int&, int&); // Call-by-reference
int main() { int a = 10, b = 15;
    cout<<"a= "<<a<<" & b= "<<b<<"to swap"<<endl;
    swap(a, b);  // Natural call
    cout<<"a= "<<a<<" & b= "<<b<<"on swap"<<endl;
}
void swap(int &x, int &y) { int t ;
    t = x; x = y; y = t;
}
```

- a= 10 & b= 15 to swap
- a= 15 & b= 10 on swap // Correct swap

- Passing values of a = 10 & b = 15
- In callee: x = 10 & y = 15
- Swapping the values of x & y
- Desired changes for the values of a & b in caller
- x & y having *same address* as a & b respectively

Program 07.05: Reference Parameter as const

- A reference parameter may get changed in the called function
- Use `const` to stop reference parameter being changed

const reference – bad

```
#include <iostream>
using namespace std;

int Ref_const(const int &x) {
    ++x;        // Not allowed
    return (x);
}
int main() { int a = 10, b;
    b = Ref_const(a);
    cout << "a = " << a <<" and"
         << " b = " << b;
}
```

- Error: Increment of read only Reference 'x'

- Compilation Error: Value of x cannot be changed
- Implies, a cannot be changed through x

const reference – good

```
#include <iostream>
using namespace std;

int Ref_const(const int &x) {

    return (x + 1);
}
int main() { int a = 10, b;
    b = Ref_const(a);
    cout << "a = " << a << " and"
         << " b = " << b;
}
```

a = 10 and b = 11

- No violation

Program 07.06: Return-by-reference

- A function can return a value by reference (Return-by-Reference)
- C uses Return-by-value

Return-by-value

```
#include <iostream>
using namespace std;
int Function_Return_By_Val(int &x) {
    cout << "x = " << x << " &x = " << &x << endl;
    return (x);
}
int main() { int a = 10;
    cout << "a = " << a << " &a = " << &a << endl;
    const int& b = // const needed. Why?
        Function_Return_By_Val(a);
    cout << "b = " << b << " &b = " << &b << endl;
}
```

```
a = 10 &a = 00DCFD18
x = 10 &x = 00DCFD18
b = 10 &b = 00DCFD00 // Reference to temporary
```

- Returned variable is *temporary*
- Has a *different address*

Return-by-reference

```
#include <iostream>
using namespace std;
int& Function_Return_By_Ref(int &x) {
    cout << "x = " << x << " &x = " << &x << endl;
    return (x);
}
int main() { int a = 10;
    cout << "a = " << a << " &a = " << &a << endl;
    const int& b = // const optional
        Function_Return_By_Ref(a);
    cout << "b = " << b << " &b = " << &b << endl;
}
```

```
a = 10 &a = 00A7F8FC
x = 10 &x = 00A7F8FC
b = 10 &b = 00A7F8FC // Reference to a
```

- Returned variable is *an alias of* a
- Has the *same address*

Program 07.07: Return-by-reference can get tricky

Return-by-reference

```
#include <iostream>
using namespace std;
int& Return_ref(int &x) {

    return (x);
}
int main() { int a = 10, b = Return_ref(a);
    cout << "a = " << a << " and b = "
         << b << endl;

    Return_ref(a) = 3; // Changes variable a
    cout << "a = " << a;
}
```

```
a = 10 and b = 10
a = 3
```

- Note how *a value is assigned to function call*
- This can change a local variable

Return-by-reference – Risky!

```
#include <iostream>
using namespace std;
int& Return_ref(int &x) {
    int t = x;
    t++;
    return (t);
}
int main() { int a = 10, b = Return_ref(a);
    cout << "a = " << a << " and b = "
         << b << endl;

    Return_ref(a) = 3; // Changes local t
    cout << "a = " << a;
}
```

```
a = 10 and b = 11
a = 10
```

- We expect a to be 3, *but it has not changed*
- It returns reference to local. This is *risky*

I/O of a Function

- In C++ we can change values with a function as follows:

I/O of Function	Purpose	Mechanism
Value Parameter	Input	Call-by-value
Reference Parameter	In-Out	Call-by-reference
`const` Reference Parameter	Input	Call-by-reference
Return Value	Output	Return-by-value Return-by-reference `const` Return-by-reference

- In addition, we can use the Call-by-address (Call-by-value with pointer) and Return-by-address (Return-by-value with pointer) as in C
- But it is neither required nor advised

Recommended Mechanisms

- **Call**
  - Pass parameters of built-in types *by* **value**
    - Recall: *Array parameters* are passed *by* **reference in C and C++**
  - Pass parameters of user-defined types *by* **reference**
    - Make a *reference parameter* `const` if it is not used for output
- **Return**
  - Return built-in types *by* **value**
  - Return user-defined types *by* **reference**
    - Return value *is not copied back*
    - May be *faster* than returning a value
    - Beware: Calling function *can change returned object*
    - Never return a local variables by reference

Difference between Reference and Pointer

Pointers	References
• Refers to an *address (exposed)* • Pointers can point to `NULL`	• Refers to an *address (hidden)* • References cannot be `NULL`

`int *p = NULL; // p is not pointing`
• Pointers can point to *different variables* at *different times*
`int a, b, *p;`
`p = &a; // p points to a`
`...`
`p = &b; // p points to b`
	`int &j ; // wrong`
	• For a reference, its *referent is fixed*
	`int a, c, &b = a; // Okay`
	`...`
	`&b = c // Error`

• `NULL` checking *is required*	• *Does not require* `NULL` checking • Makes code *faster*
• *Allows* users to *operate on the address* • diff pointers, increment, etc. • Array of pointers can be *defined*	• *Does not allow* users to *operate on the address* • All operations are interpreted for the referent • Array of references *not allowed*

Module Summary

- Introduced reference in C++
- Studied the difference between call-by-value and call-by-reference
- Studied the difference between return-by-value and return-by-reference
- Discussed the difference between References and Pointers
